

Taylor towers for Γ -modules

by Birgit Richter

Abstract

We consider Taylor approximation for functors from the small category of finite pointed sets Γ to modules and give an explicit description for the homology of the layers of the Taylor tower. These layers are shown to be fibrant objects in a suitable closed model category structure. Explicit calculations are presented in characteristic zero including an application to higher order Hochschild homology and a spectral sequence for the homology of the homotopy fibres of this approximation is provided. [†]

1 Introduction

Similarly to the Taylor series for smooth functions in differential calculus T. Goodwillie [G] associates a Taylor tower

$$\begin{array}{c}
 \vdots \\
 \downarrow \\
 P_{n+1}F \\
 \uparrow \downarrow \\
 P_nF \\
 \uparrow \downarrow \\
 P_{n-1}F \\
 \vdots \\
 \downarrow \\
 P_1F \\
 \downarrow \\
 P_0F = F(*)
 \end{array}$$

$F \xrightarrow{\quad} P_1F$
 $F \xrightarrow{\quad} P_0F$

[†]Keywords: Taylor tower, cubical construction, dual of the Steenrod algebra
 Mathematics Subject Classification: 18A25, 18G10, 55P65

to endofunctors of topological spaces F which preserve weak homotopy equivalences. This approximation converges to F and the $P_n F$ are n -excisive functors, i.e. they can be thought of as degree n approximations of the functor F .

In this paper we will consider endofunctors of simplicial sets, which arise from Γ -modules, i.e. functors from the category of finite pointed sets Γ to the category of R -modules, for some ring R . Any Γ -module can be extended to an endofunctor of simplicial sets by extending it degreewise to a functor from pointed simplicial sets to simplicial modules.

Working in the category of Γ -modules has the advantage that one can use the tools of homological algebra in order to understand the homology of the approximation steps $H_k P_n F : \Gamma \rightarrow R$ and the homology of the homotopy fibre $D_n F := \text{hfib}(P_n F \rightarrow P_{n-1} F)$ and to describe these homologies in terms of derived functors.

Fitting to the Taylor tower there exist a tower of model category structures, which are localizations of the usual model structure for Γ -chain complexes at the functors $P_n(-)$. Homologically degree n functors are then the fibrant objects in the n -th model category structure.

The homology of the homotopy fibre can be determined in characteristic zero for an important family $(\psi_\ell)_\ell$ of Γ -modules. This leads to an explicit calculation of higher order Hochschild homology of the truncated polynomial algebra $\mathbb{K}[x]/x^2$.

As an important example we consider the functor $St : \Gamma \rightarrow \mathbb{F}_2 - \mathbf{Vect}$ from finite pointed sets to \mathbb{F}_2 -vector spaces given by $St[n] := \mathbb{F}_2\{\overline{\mathbb{F}_2}[n]\}$. The homotopy of this functor when prolonged to pointed simplicial sets gives the \mathbb{F}_2 -homology of Eilenberg-MacLane spaces. With the isomorphism $H_* P_1(St)[1] \cong \pi_*^{st}(St)$ we see that $H_* P_1(St)[1]$ is the dual of the Steenrod algebra over \mathbb{F}_2 .

We prove that this functor splits as $St = \bigoplus \psi_\ell$. We calculate the homology of the homotopy fibres $D_n(\psi_\ell)$ in the approximation of these functors for ℓ small and for a certain range of approximation with the help of a spectral sequence which we develop in section 7.

Acknowledgements – This work is part of my thesis and I would like to thank C.-F. Bödigheimer, V. Franjou and T. Pirashvili for supporting this project. It is a pleasure to thank the referee for his corrections and suggestions.

2 Γ -modules

Let Γ be the category of finite pointed sets and pointed maps. We assume that the objects of Γ are the pointed sets $[n] = \{0, 1, \dots, n\}$ with 0 as a basepoint. If the cardinality of the set is not important we denote an object of Γ by X_+ where X is a finite set and $+$ is an added basepoint. We call functors F from Γ in a category of R -modules just Γ -modules. Here R is a commutative ring with unit. For an arbitrary set S we denote by $R\{S\}$ the free R -module generated by S .

2.1 Examples

1. The functors $\Gamma^n : \Gamma \rightarrow R\text{-mod}$, $n \geq 0$, which take $[m] \in \Gamma$ to the free R -module generated by the morphisms from $[n]$ to $[m]$

$$\Gamma^n[m] = R\{\Gamma([n], [m])\}$$

are projective generators of the category of all Γ -modules. The contravariant representable functors Γ_n are defined analogously

$$\Gamma_n[m] = R\{\Gamma([m], [n])\}.$$

2. The cokernel of the transformation from Γ^0 to Γ^1

$$L := \text{coker}(\Gamma^0 \rightarrow \Gamma^1)$$

sends a finite pointed set $[n]$ to the free R -module generated by the elements of $\{1, \dots, n\}$.

3. The pointwise tensor product of two Γ -modules F and G is defined as

$$(F \otimes G)[n] := F[n] \otimes G[n].$$

Important examples of Γ -modules are the n -fold tensor product $L^{\otimes n}$ of L , the n -th exterior product $\Lambda^n \circ L$ and the n -th symmetric product $\text{Sym}^n \circ L$.

2.2 Prolongation to simplicial sets

Every Γ -module F gives rise to a functor from pointed simplicial sets to simplicial R -modules: On an arbitrary pointed set X_+ the functor F is defined via colimits

$$F(X_+) = \operatorname{colim}_{\substack{S_+ \subset X_+ \\ |S_+| < \infty}} F(S_+),$$

and for a pointed simplicial set X_\bullet the simplicial R -module $F(X)_\bullet$ is defined as $F(X)_n := F(X_n)$.

2.3 Cross-effects

The n -th cross-effect $cr_n F$ of a Γ -module F is a functor

$$cr_n F : \underbrace{\Gamma \times \dots \times \Gamma}_n \rightarrow R\text{-mod}$$

which is defined as

$$cr_n F(X_+^1, \dots, X_+^n) := \operatorname{Image} \left(\sum_{k=1}^n (-1)^{n-k} \sum_{i_1 < \dots < i_k} F(\pi_{(X_+^{i_1} \vee \dots \vee X_+^{i_k})}) \right)$$

Here $\{i_1, \dots, i_k\}$ is a subset of $\{1, \dots, n\}$ and the

$$\pi_{(X_+^{i_1} \vee \dots \vee X_+^{i_k})} : F(X_+^1 \vee \dots \vee X_+^n) \rightarrow F(X_+^1 \vee \dots \vee X_+^n)$$

are the projection maps on the components $X_+^{i_1}, \dots, X_+^{i_k}$. An alternative and useful definition is the following: Let $r_i : [n] \rightarrow [n-1]$ be the map which is given by

$$r_i(j) = \begin{cases} j, & j < i \\ 0, & j = i \\ j-1, & j > i. \end{cases}$$

Then the above definition of the n -th cross-effect evaluated on $([1], \dots, [1])$ is equivalent to $cr_n F([1], \dots, [1]) = \bigcap_{i=1}^n \ker F(r_i)$.

The functor $cr_n F$ measures the failure of F to be of degree $n-1$. For endofunctors of abelian groups cross-effects are defined in [E-M2, §§8,9].

Examples Linear functors F from Γ to abelian groups give rise to Eilenberg-MacLane spectra: The evaluation of such an F on a simplicial model of the n -sphere \mathbb{S}^n is a $K(F[1], n)$. Typical degree n functors are $L^{\otimes n}$, $\Lambda^n \circ L$ and $\operatorname{Sym}^n \circ L$.

2.4 Dold-Kan correspondence

Let Ω denote the category of nonempty finite sets and surjections. We denote the objects of Ω by $\underline{n} = \{1, \dots, n\}$. There is a Dold-Kan correspondence (see [P2]) between the category of functors from Γ to $R\text{-mod}$ and the category of functors from Ω to $R\text{-mod}$. For every Γ -module $F : \Gamma \rightarrow R\text{-mod}$ there is a corresponding functor $cr(F) : \Omega \rightarrow R\text{-mod}$ defined by

$$cr(T)(\underline{n}) = cr_n T([1], \dots, [1]).$$

A surjection $f : \underline{n} \rightarrow \underline{m}$ gives rise to a map of finite pointed sets f^+ and such a map sends the intersection of the kernels of the $T(r_i)$ again to an intersection of such kernels and hence f induces a map $cr(f^+) : cr(F)(\underline{n}) \rightarrow cr(F)(\underline{m})$. In [P2, 3.1] Pirashvili shows that this transformation

$$cr : R\text{-mod}^\Gamma \rightarrow R\text{-mod}^\Omega$$

is an equivalence of categories.

3 Taylor approximation for Γ -modules

Let $\text{Ch}(R)$ denote the category of non-negative chain complexes of R -modules. We will build an approximation tower for Γ -modules:

$$\cdots \rightarrow P_n F \rightarrow P_{n-1} F \rightarrow \cdots \rightarrow P_1 F \rightarrow P_0 F$$

where the functors $P_n F : \Gamma \rightarrow \text{Ch}(R)$ are homologically of degree n .

Definition 3.1 *A functor $F : \Gamma \rightarrow \text{Ch}(R)$ is called homologically of degree $\leq n$ if $cr_{n+1}(F)$ is acyclic.*

We will give an explicit construction of this tower for Γ -modules. The properties of the approximation are straightforward to see with the help of the cotriple approach of Johnson and McCarthy [J-McC2, 2.8]:

- The n -th approximation $P_n F$ is homologically of degree n .
- The map $P_n F \rightarrow P_n P_n F$ is a weak equivalence.
- A Γ -chain complex is homologically of degree n iff $F \rightarrow P_n F$ is a weak equivalence.
- The transformation $P_n : R\text{-mod}^\Gamma \rightarrow \text{Ch}(R)^\Gamma$ is exact.

3.1 Construction of the approximation steps

The construction we give here is similar to the one in [J-McC1] and for the readers who are familiar with the work of B. Johnson and R. McCarthy we cite the corresponding definitions and statements from [J-McC1] in the appropriate places. Before we define the approximation steps $P_n F$ we will give an unnormalized version $P'_n F$. The unnormalized approximation in degree n is a functor $P'_n F$ from Γ to chain complexes whose k -dimensional component is given by

$$P'_n F(X_+)_k := F\left(\bigvee_{[n]^k} X_+\right).$$

We define $(P'_n F(X_+))_0$ as $F(X_+)$. The boundary map

$$\delta : P'_n F(X_+)_k = F\left(\bigvee_{[n]^k} X_+\right) \rightarrow F\left(\bigvee_{[n]^{k-1}} X_+\right) = P'_n F(X_+)_{k-1}$$

is induced by maps on set level

$$\bigvee_{[n]^k} X_+ \rightarrow \bigvee_{[n]^{k-1}} X_+.$$

Let π_1^j be the projection,

$$\pi_1^j : \bigvee_{[n_1] \times \dots \times [n_j] \times \dots \times [n_k]} X_+ \rightarrow \bigvee_{[n_1] \times \dots \times [n_j - 1] \times \dots \times [n_k]} X_+$$

which maps all components X_+ with labels $(x_1, \dots, x_{j-1}, n_j, x_{j+1}, \dots, x_k)$ to the basepoint and let π_2^j be the map that projects everything labelled by $(x_1, \dots, x_{j-1}, n_j - 1, x_{j+1}, \dots, x_k)$ to the basepoint. All other elements are mapped identically. In addition we consider $\pi_{>}^j$ which overlaps the components with labels n_j and $n_j - 1$ in the j -th place and is the identity on all other elements (compare [J-McC1, Def. 1.1,1.2]).

Now define the j -th part of the boundary δ as

$$\delta_j := -F(\pi_1^j) - F(\pi_2^j) + F(\pi_{>}^j).$$

The full boundary map

$$\delta : F\left(\bigvee_{[n]^k} X_+\right) \longrightarrow F\left(\bigvee_{[n]^{k-1}} X_+\right)$$

is the alternating sum of n -fold iterations of δ_j

$$\delta := \sum_{j=1}^k (-1)^j \delta_j^n.$$

A proof that this defines in fact a boundary map for the unnormalized approximation $P'_n F$ is an easy modification of the proof in [J-McC1, Prop. 1.4] and can be found in [R, pp. 31,32].

Example For $n = 2$ the boundary map $\delta : (P'_2 F)_1 \rightarrow (P'_2 F)_0$ is induced by the projections π_1^1 and π_2^1 and the map $\pi_{>}^1$ which folds the second and third component

$$\begin{array}{ccc} \begin{array}{ccc} X_+ & \xrightarrow{\quad} & X_+ \\ \downarrow & & \downarrow \\ X_+ & \xrightarrow{\quad} & X_+ \\ \downarrow & & \downarrow \\ X_+ & \xrightarrow{\quad} & X_+ \end{array} & \begin{array}{ccc} X_+ & & X_+ \\ \downarrow & \searrow & \\ X_+ & \xrightarrow{\quad} & X_+ \\ \downarrow & & \downarrow \\ X_+ & \xrightarrow{\quad} & X_+ \end{array} & \begin{array}{ccc} X_+ & & X_+ \\ \downarrow & \searrow & \\ X_+ & \xrightarrow{\quad} & X_+ \\ \downarrow & & \downarrow \\ X_+ & \xrightarrow{\quad} & X_+ \end{array} \\ \downarrow & & \downarrow \\ X_+ & \xrightarrow{\quad} & X_+ \end{array}$$

and by the iteration of these maps.

We normalize the chain complexes $P'_n F(X_+)$ and build the quotient concerning “ i -slabs” and “diagonal” elements. Let us denote the corresponding subsets in $[n]^k$ with the same name. The family of subsets which build i -slabs are

$$S_j^i := \{(x_1, \dots, x_k) \mid x_i \neq j\}, \quad 0 \leq j \leq n$$

whereas the diagonals are the subsets of the form

$$D_i := \{(x_1, \dots, x_k) \mid x_i = x_{i+1}\}.$$

Definition 3.2 *The n -th Taylor approximation $P_n F$ of an Γ -module F in dimension k is the cokernel*

$$(P_n F(X_+))_k := \text{coker} \left(\bigoplus_{T \in \{\{S_j^i\}, \{D_i\}\}} F(\bigvee_{t \in T} X_+) \longrightarrow F(\bigvee_{s \in [n]^k} X_+) \right).$$

The maps for this cokernel are induced by the inclusions $T \subset [n]^k$.

Remark 3.3 *It is straightforward to check that the boundary map δ is well-defined on the quotient (see [J-McC1, Lemma 1.11]).*

Remark 3.4 *This normalization is necessary for the properties the $P_n F$ should have: The unnormalized approximation P'_n is given by evaluating F on a sum. From the definition of the cross-effect it follows that such a term is isomorphic to a sum of cross-effects. If we consider the normalized term $P_n F$ then in the ℓ -th chain degree this is isomorphic to*

$$(P_n F)_\ell \cong \bigoplus_{S \subset [n]^\ell} cr_{|S|} F$$

where S runs over all non-degenerate subsets, i.e. subsets which are neither slabs nor diagonals, of $[n]^\ell$ (see [J-McC1, Prop. 3.8]). As a subset S with $|S| \leq n$ is always degenerate, this ensures among other things that $F \rightarrow P_n F$ is a weak equivalence iff F is of homological degree n .

3.2 The cubical construction

Let A be an abelian group. We consider the functor $F = \mathbb{Z}\{\overline{A}\{-}\}$, which maps a finite pointed set $[n]$ to the free abelian group generated by the elements of A^n . The Eilenberg-MacLane cubical construction $Q(A)$ which was defined in [E-M1, § 12, p.321] is the first Taylor approximation of $\mathbb{Z}\{\overline{A}\{-}\}$ evaluated on $[1] \in \Gamma$:

$$P_1(\mathbb{Z}\{\overline{A}\{-}\})[1] = Q_*(A).$$

Hence $Q_*(A)$ is a chain complex of abelian groups which is a quotient of $\mathbb{Z}\{A^{2^m}\}$ in degree m .

In degree zero the nontrivial generators are of the form (a) with $0 \neq a \in A$; in degree one the generators are (a, b) with $a, b \neq 0$. In degrees zero, one and two the boundary map looks as follows:

$$\begin{aligned} \delta(a) &= 0, \\ \delta(a, b) &= (a + b) - (a) - (b), \\ \delta_{(c,d)}^{(a,b)} &= -(a, b) - (c, d) + (a + c, b + d) \\ &\quad + (a, c) + (b, d) - (a + b, c + d). \end{aligned}$$

We abbreviate the n -th Taylor approximation of $F = \mathbb{Z}\{\overline{A}\{-}\}$ evaluated at $[1]$ with

$$Q_*^n(A) := P_n(\mathbb{Z}\{\overline{A}\{-}\})[1]$$

and call this chain complex the n -th cubical construction on A .

3.3 The connections inside the tower

As in the additive case there are natural transformations $F \rightarrow P_n F$ and $P_n F \rightarrow P_{n-1} F$ for every n (compare [J-McC1, Lemma 1.15]). From now on we assume that our functors F are reduced i.e. $F[0] = 0$. This is no actual restriction because the part $F[0]$ always splits as a direct summand and we can consider the reduced part F' defined by $F(X_+) \cong F'(X_+) \oplus F[0]$. The Taylor approximation of F is then essentially the one of F' because $P_n F \cong F[0] \oplus P_n F'$.

Proposition 3.5 *The maps $F([\ell]) \mapsto (P_n F([\ell]))_0$ induce natural transformations*

$$p_n : F \rightarrow P_n F.$$

□

The different layers of the Taylor tower can be connected by the following maps:

Proposition 3.6 *There are natural transformations*

$$q_n : P_n F \rightarrow P_{n-1} F$$

such that the triangles

$$\begin{array}{ccc} & P_n F & \\ & \nearrow & \downarrow \\ F & \longrightarrow & P_{n-1} F \end{array} \quad \text{commute.}$$

Proof In degree zero the map q_n is just the identity because the modules $(P_n F(X_+))_0$ and $(P_{n-1} F(X_+))_0$ are the same. For degree k greater than 0 we define the map

$$(q_n)_k : (P_n F)_k \rightarrow (P_{n-1} F)_k$$

as the following composition:

$$(q_n)_k = \delta_1 \circ \cdots \circ \delta_k.$$

It is easy to see, that these maps are in fact chain maps. A proof can be found in [R]. It works similar to the proof of [J-McC1, Lemma 1.7]. □

4 Homology of the approximation steps

4.1 Higher cubical constructions in the set context

For the interpretation of the homology of the usual Eilenberg-MacLane cubical construction Q_* it was helpful to introduce an auxiliary complex SQ_* . T. Pirashvili related in [P1] this complex to the homology of $Q_*(A)$ - which is the homology of the first approximation P_1 applied to the functor $\mathbb{Z}\{\overline{A}\{-}\}$ - and to the stable homology of Eilenberg-MacLane spaces. The generalized version of SQ_* which we introduce in this section will help us to gain a description of the homology of the higher cubical constructions.

Let $X_+ \in \Gamma$. Define $\widetilde{SQ}_k^{(n)}(X_+)$ to be the free module generated by $[n]^k$ -tuples of pairwise disjoint subsets of X , i.e. $\widetilde{SQ}_0^{(n)}(X_+)$ is generated by $(S), S \subset X$ and $\widetilde{SQ}_1^{(n)}(X_+)$ has elements like $\chi = (S_0, \dots, S_n)$ with $S_i \cap S_j = \emptyset, (i \neq j), S_i \subset X$ as a basis. We denote elements of $\widetilde{SQ}_k^{(n)}(X_+)$ as functions $\chi(\varepsilon_1, \dots, \varepsilon_k)$ with $\varepsilon_i \in [n]$. The value of χ on such a k -tuple is the corresponding subset of X .

The functor $\widetilde{SQ}_*^{(n)}$ is contravariant: For a morphism $f : X_+ \rightarrow Y_+$ the induced map from $\widetilde{SQ}_*^{(n)}(Y_+)$ to $\widetilde{SQ}_*^{(n)}(X_+)$ takes the preimage of the subsets. The case $n = 1$ has already been defined in [P1].

The boundary map $\delta : \widetilde{SQ}_k^{(n)}(X_+) \rightarrow \widetilde{SQ}_{k-1}^{(n)}(X_+)$ is defined analogously to the one for $P_n F$ and we use similar projection maps: The map π_1^i removes all subsets in $\widetilde{SQ}_k^{(n)}(X_+)$ with label n in the i -th coordinate whereas π_2^i removes the ones labelled by $n - 1$ in the i -th place. The map $\pi_{>}^i$ takes the union of the subsets labelled by n and $n - 1$ in the coordinate ε_i . Again let δ_i denote $\pi_{>}^i - \pi_1^i - \pi_2^i$. The boundary δ is the alternating sum of the n -fold iterations of the δ_i :

$$\delta = \sum_{i=1}^k (-1)^i \delta_i^n.$$

For $k = 1$ and $n = 2$, δ maps a generator (S, T, U) to:

$$\delta(S, T, U) = (S \cup T \cup U) - (S \cup T) - (S \cup U) - (T \cup U) + (S) + (T) + (U).$$

The final complex $SQ_k^{(n)}(X_+)$ is the quotient of $\widetilde{SQ}_k^{(n)}(X_+)$ by all elements, which have the empty set as a value in one hyperplane, i.e. genera-

tors χ with $\chi(\varepsilon_1, \dots, \varepsilon_{i-1}, j, \varepsilon_{i+1}, \dots, \varepsilon_k) = \emptyset$ for a $j \in [n]$ and by diagonal elements, i.e. χ with $\chi(\varepsilon_1, \dots, \varepsilon_k) = \emptyset$ if $(\varepsilon_1, \dots, \varepsilon_k) \in [n]^k$, and $\varepsilon_i \neq \varepsilon_{i+1}$.

4.2 The homological degree of $SQ_*^{(n)}$

The higher cubical constructions in the set context $SQ_*^{(n)}$ are crucial for the calculation of the homology of the higher cubical constructions for functors. Recall from 3.1 that a functor is homologically of degree $\leq n$ if its $(n+1)$ -st cross-effect is acyclic.

Proposition 4.1 *The functor $SQ_*^{(n)} : \Gamma^{op} \rightarrow \text{Ch}(R)$ is homologically of degree n .*

Proof There is an explicit chain homotopy which proves the claim. For a generator

$$\chi(\varepsilon_1, \dots, \varepsilon_k) \in SQ_k^{(n)}(X_+^0 \vee \dots \vee X_+^n)$$

we define a map \mathcal{H} to $SQ_{k+1}^{(n)}(X_+^0 \vee \dots \vee X_+^n)$ via

$$\mathcal{H}(\chi)(i, \varepsilon_1, \dots, \varepsilon_k) := \chi(\varepsilon_1, \dots, \varepsilon_k) \cap X^i \quad \text{for } 0 \leq i \leq n.$$

This gives a homotopy between the zero map and the map whose image is the $(n+1)$ st cross-effect. \square

4.3 The homology of the higher Q -constructions

Definition 4.2 *The n -th Q -construction of a functor $F : \Gamma \rightarrow R\text{-mod}$ is defined as*

$$Q_*^{(n)}(F) := SQ_*^{(n)} \otimes_{\Gamma} F \in \text{Ch}(R).$$

It is easy to see that

$$P_n F[1] \cong Q_*^{(n)}(F)$$

because $\widetilde{SQ}_i^{(n)} \otimes_{\Gamma} F \cong \Gamma_{[n]^i} \otimes_{\Gamma} F \cong F([n]^i)$ and the submodules generated by the relations map isomorphically.

The homology of the n -th Q -construction $Q_*^{(n)}(F)$ has an interpretation as a Tor -functor, because $SQ_*^{(n)}$ is a projective resolution of a functor, which we define now:

Let $\mathcal{B}_n : \Gamma \rightarrow R\text{-mod}$ be the functor which maps a finite pointed set S_+ to the free module generated by all nonempty subsets of S with cardinality

less or equal to n . On morphisms $\mathcal{B}_n(f)$ takes the image of a set if the image does not contain zero; if $0 \in \text{im}(f)$ then the induced map is zero. Now define $t^n : \Gamma^{op} \rightarrow R\text{-mod}$ as the dual functor of \mathcal{B}_n , i.e. $t^n(S_+) = \text{Hom}_R(\mathcal{B}_n(S_+), R)$.

Lemma 4.3 *The functor t^n is of degree n .*

Proof We will prove this claim by an inductive argument. For $n = 1$ it is obvious that $t = t^1$ is additive. Consider the canonical exact sequence

$$0 \rightarrow \mathcal{B}_{n-1} \rightarrow \mathcal{B}_n \rightarrow \mathcal{B}_n/\mathcal{B}_{n-1} \rightarrow 0.$$

The dual of this sequence is again exact. Hence the functors t^n fit in the following exact sequence of functors from Γ^{op} to $R\text{-mod}$

$$0 \rightarrow \theta^n \rightarrow t^n \rightarrow t^{n-1} \rightarrow 0$$

where θ^n is the dual of the quotient $\mathcal{B}_n/\mathcal{B}_{n-1}$, i.e. $\theta^n(S_+)$ is dual to the free module generated by subsets of S of cardinality exactly n . Clearly the functor θ^n is of degree n . With the exactness of the cross-effect it follows that $cr_{n+1}t^n = 0$.

□

Lemma 4.4 *The Γ -chain complex $SQ_*^{(n)}$ is a projective resolution of a degree n functor which is isomorphic to t^n .*

Proof The projectivity of the $SQ_*^{(n)}$ is clear because they are quotients of the projective generators Γ_S with $S = [n]^i$ where $\Gamma_S(X_+) = R\{\Gamma(X_+, S)\}$ and there is a section from $SQ_*^{(n)}$ to $\widetilde{SQ}_*^{(n)}$ (compare the argument in [J-P], 2.3). We have to prove that the homology of $SQ_*^{(n)}$ vanishes in positive dimensions and that its zeroth homology is a functor isomorphic to t^n .

It follows from the definition of $SQ_*^{(n)}$ that

$$SQ_i^{(n)}[\ell] = 0 \quad \forall i > 0 \quad \text{and} \quad \ell \leq n$$

In general $SQ_*^{(n)}$ has only homology in degree 0 because its homology is polynomial of degree n and for $[1], \dots, [n]$ there is no homology in higher degrees.

We now prove that

$$H_0 SQ_*^{(n)} \cong t^n$$

With the Dold-Kan correspondence of 2.4 we have to show that this zeroth homology and t^n have the same cross effects. On an object $X_+ \in \Gamma$ the module $H_0(SQ_*^{(n)})(X_+)$ is generated by subsets $S \subset X$ with cardinality $|S| \leq n$. If $f : X_+ \rightarrow Y_+$ is a morphism in Γ , then the induced map $f^* : H_0(SQ_*^{(n)})(Y_+) \rightarrow H_0(SQ_*^{(n)})(X_+)$ takes the equivalence class of the preimages: If the cardinality of $f^{-1}(S)$ is less or equal to n , then $f^*(S) = f^{-1}(S)$; otherwise $f^{-1}(S) \in H_0(SQ_*^{(n)})$ is equivalent to some alternating sum of subsets with cardinality $\leq n$. The degree of $H_0SQ_*^{(n)}$ is n . Its i -th cross effect $cr_i H_0(SQ_*^{(n)})(X_+^0, \dots, X_+^i)$ is given by the cokernel of

$$\bigoplus_{j=0}^i H_0(SQ_*^{(n)})(X_+^0 \vee \dots \vee \check{X}_+^j \vee \dots \vee X_+^i) \xrightarrow{\bigoplus r_j^*} H_0(SQ_*^{(n)})(X_+^0 \vee \dots \vee X_+^i).$$

It is easy to see that the cross effects $cr_i(H_0(SQ_*^{(n)}))([1], \dots, [1])$ are one-dimensional for $i \leq n$. They vanish for $i > n$ because $H_0(SQ_*^{(n)})$ is of degree n . The identification of $\{1, \dots, i\}$ in $cr_i(H_0(SQ_*^{(n)}))$ with $\{1, \dots, i\}^*$ in $cr_i(t^n)$ induces a natural isomorphism. \square

As we have this projective resolution the homology of the higher Q -constructions is given by:

Theorem 4.5

$$H_*Q_*^{(n)}(F) = H_*(SQ_*^{(n)} \otimes_{\Gamma} F) = \mathrm{Tor}_*^{\Gamma}(t^n, F)$$

\square

For a chain complex C_* we denote by $sh_1 C_*$ the shifted chain complex, i.e. $(sh_1 C_*)_k = C_{k-1}$.

Definition 4.6 *The n -th homotopy fibre of the Taylor tower is defined as $D_n F_* = \mathrm{cone}_{*+1}(q_n : P_n F \rightarrow P_{n-1} F)$.*

Proposition 4.7 *The homology of the n -th homotopy fibre $D_n F_*$ is given as a derived functor of a Γ -module of degree n , namely*

$$H_*(D_n F[1]) = \mathrm{Tor}_*^{\Gamma}(\theta^n, F).$$

Proof We will prove that the functor $F \mapsto H_*(D_n F[1])$ fulfills the universal properties of the Tor -functor, i.e. we have to show

1) $H_*(D_n(-)[1])$ maps short exact sequences of functors to long exact sequences.

2) The functors $H_*(D_n(-)[1])$ and $\text{Tor}_*^\Gamma(\theta^n, -)$ coincide on projective objects.

1) Let $0 \rightarrow F' \rightarrow F \rightarrow F'' \rightarrow 0$ be a short exact sequence of functors. We have to show that $H_*(D_n(-)[1])$ maps this sequence to a long exact sequence

$$\begin{array}{ccccccc} & & & & \cdots & \longrightarrow & H_{\ell+1}(D_n(F'')[1]) \\ \longrightarrow & H_\ell(D_n(F')[1]) & \longrightarrow & H_\ell(D_n(F)[1]) & \longrightarrow & H_\ell(D_n(F'')[1]) & \\ \longrightarrow & H_{\ell-1}(D_n(F')[1]) & \longrightarrow & \cdots & & & \end{array}$$

The functor $F \mapsto P_n F[1]$ is exact, hence for every short exact sequence as above we have the following array of commutative diagrams:

$$\begin{array}{ccccccc} & & 0 & & 0 & & 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & P_{n-1}F'[1] & \longrightarrow & P_{n-1}F[1] & \longrightarrow & P_{n-1}F''[1] \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & sh_1 D_n F'[1] & \longrightarrow & sh_1 D_n F[1] & \longrightarrow & sh_1 D_n F''[1] \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ 0 & \longrightarrow & sh_1 P_n F'[1] & \longrightarrow & sh_1 P_n F[1] & \longrightarrow & sh_1 P_n F''[1] \longrightarrow 0 \\ & & \downarrow & & \downarrow & & \downarrow \\ & & 0 & & 0 & & 0 \end{array}$$

As the composition $D_n F'[1] \rightarrow D_n F''[1]$ vanishes, we can apply the 3×3 -lemma and obtain that $0 \rightarrow D_n F'[1] \rightarrow D_n F[1] \rightarrow D_n F''[1] \rightarrow 0$ is a short exact sequence of chain complexes and the claim is proved.

2) To make the two functors coincide we have to show that they have the same value on projectives. The short exact sequence

$$0 \rightarrow P_{n-1}F[1] \rightarrow D_n F[1] \rightarrow P_n F[1] \rightarrow 0$$

leads to the usual long exact sequence in homology

$$\begin{array}{ccccccc} \cdots & \longrightarrow & H_{k+1}P_{n-1}F[1] & \longrightarrow & H_k D_n F[1] & \longrightarrow & H_k P_n F[1] \longrightarrow \\ & & \longrightarrow & & \cdots & & \end{array}$$

Thus it is clear that $H_k D_n F[1]$ vanishes for $k > 0$ if F is projective. For $k = 0$ we obtain that $H_0 D_n F[1] \cong (t^n \otimes_{\Gamma} F)/(t^{n-1} \otimes_{\Gamma} F)$ and this can be identified with $\theta^n \otimes_{\Gamma} F$. □

5 Model category structures

The aim of this part is to give model category structures on Γ -chain complexes, which fit to the Taylor tower, i.e. the n -th approximation step should be fibrant in the right setting.

For Γ -chain complexes there is a standard model category structure, because the category of Γ -chain complexes is the same as the category of chain complexes of Γ -modules and this category has the usual structure such that

- weak equivalences are isomorphisms in homology,
- cofibrations are degreewise splitting monomorphisms with projective cokernel and
- fibrations are morphisms which are surjective in positive degrees.

So typically the cokernel of a cofibration is a direct sum of standard projective generators Γ^k .

Remark 5.1 *It is straightforward to see that this model category structure is proper.*

5.1 Model category structures fitting to the Taylor tower

We want to define a fitting model category structure for each approximation step in the Taylor tower. "Fitting" means that the weak equivalences should be the $H_* P_n$ -isomorphisms. To this end we have to localize the standard model category on Γ -chain complexes. O. Renaudin gained in [Re] similar structures via constructing localizing subcategories.

The model category of Γ -chain complexes is proper. We change the model structure and call a map f a $P_n(-)$ -equivalence if $P_n(f)$ is a weak equivalence in the standard structure. A map f is a P_n -fibration if it has the right lifting property concerning all ordinary cofibrations which are $P_n(-)$ -equivalences.

We denote this structure by \mathcal{T}_n . The functors $P_n(-)$ have three especially good properties:

1. The functors $P_n(-)$ preserve weak equivalences.
2. The maps $(p_n)_{P_n(F)} : P_n F \rightarrow P_n P_n F$ are weak equivalences.
3. The class of the $P_n(-)$ -equivalences is closed concerning pullbacks along $P_n(-)$ -fibrations and pushouts along cofibrations.

The third property is a consequence of the exactness of the functors $P_n(-)$; hence $H_* P_n(-)$ is a homology theory. In this situation \mathcal{T}_n is again a proper model category. Bousfield and Friedlander [B-F] proved this for simplicial model categories; Goerss and Jardine give a more general proof in [Go-J].

Theorem 5.2 [Go-J, X, Theorem 4.1] *Given a closed and proper model category \mathcal{C} and given an endofunctor $Q : \mathcal{C} \rightarrow \mathcal{C}$ with a natural transformation $\eta : Id \rightarrow Q$ and with the properties 1,2 and 3 above, there is a proper and closed model category structure on \mathcal{C} , so that the weak equivalences are the $Q(-)$ -equivalences, the cofibrations stay as they were in the former structure and the fibration are determined by the right lifting property.*

The fibrant objects in the model category for $Q = P_n$ are exactly the functors F , for which the transformation $(p_n)_F : F \rightarrow P_n F$ is a weak equivalence of Γ -chain complexes (see [Go-J], X, Corollary 4.12), hence the functors of homological degree n are fibrant. In particular the approximation steps $P_n F$ are fibrant in \mathcal{T}_n .

6 Calculation of $\mathrm{Tor}_*(\theta^m, \psi_n)$ in characteristic zero

In this section the ground field \mathbb{K} is of characteristic zero. We will give a complete calculation of the homology of the homotopy fibres D_n of the functors $\psi_m = \mathcal{B}_m/\mathcal{B}_{m-1}$. These Γ -vector spaces possess a Koszul-like resolution (see [P3]). For odd degrees ($m = 2k + 1$) one has

$$0 \rightarrow \Lambda^k \circ L \otimes \mathrm{Sym}^1 \circ L \rightarrow \cdots \rightarrow \mathrm{Sym}^{2k+1} \circ L \rightarrow \psi_{2k+1} \rightarrow 0$$

whereas for even degrees ($m = 2k$) the resolution looks as follows:

$$0 \rightarrow \Lambda^k \circ L \rightarrow \Lambda^{k-1} \circ L \otimes \mathrm{Sym}^2 \circ L \rightarrow \cdots \rightarrow \mathrm{Sym}^{2k} \circ L \rightarrow \psi_{2k} \rightarrow 0.$$

The maps $\Lambda^{i+1} \circ L \otimes \text{Sym}^j \circ L \rightarrow \Lambda^i \circ L \otimes \text{Sym}^{j+2} \circ L$ in the sequences are

$$(x_0 \wedge \dots \wedge x_i) \otimes (y_1 \cdots y_j) \mapsto \sum_{h=0}^i (x_0 \wedge \dots \wedge \check{x}_h \wedge \dots \wedge x_i) \otimes (x_h^2 y_1 \cdots y_j)$$

and

$$\begin{aligned} \text{Sym}^m \circ L &\rightarrow \psi_m \\ y_1 \cdots y_m &\mapsto \{y_1, \dots, y_m\} \pmod{\mathcal{B}_{m-1}} \end{aligned}$$

Proposition 6.1 *Let $i + j$ be m . The tensor products which are needed for the calculation of $\text{Tor}_*^\Gamma(\theta^n, \psi_m)$ are*

$$\theta^n \otimes_\Gamma (\Lambda^i \circ L \otimes \text{Sym}^j \circ L) = \begin{cases} \mathbb{K} & \text{for } m = n, i = 0, 1 \\ 0 & \text{else.} \end{cases}$$

Proof If $m < n$ then the degree of $F_{i,j} := \Lambda^i \circ L \otimes \text{Sym}^j \circ L$ with $i + j = m$ is m and hence smaller than n . This gives us

$$\theta^n \otimes_\Gamma F_{i,j} \cong cr(\theta^n) \otimes_\Omega cr(F_{i,j}) \cong (\mathbb{K} \otimes_\Omega cr(F_{i,j})(\underline{n})) / \sim = 0.$$

Now let m be greater than n . There is a sequence of surjections

$$t^{\otimes n} \twoheadrightarrow \text{Sym}^n \circ t \twoheadrightarrow \theta^n.$$

As we assumed that the characteristic of \mathbb{K} is zero $F_{i,j}$ is a direct summand of $L^{\otimes m}$ and we obtain a surjection

$$t^{\otimes n} \otimes_\Gamma L^{\otimes m} \twoheadrightarrow t^{\otimes n} \otimes_\Gamma F_{i,j} \twoheadrightarrow \theta^n \otimes_\Gamma F_{i,j}.$$

For a contravariant functor T the cross-effect is $cr_m(T) = \text{coker}(\bigoplus_{i=1}^m T[m-1] \rightarrow T[m])$. Taking the exact sequence

$$\bigoplus_{i=1}^m \Gamma^{m-1} \rightarrow \Gamma^m \rightarrow L^{\otimes m} \rightarrow 0$$

and tensoring it with T gives

$$\begin{array}{ccccccc} T \otimes_\Gamma (\bigoplus_{i=1}^m \Gamma^{m-1}) & \longrightarrow & T \otimes_\Gamma \Gamma^m & \longrightarrow & T \otimes_\Gamma L^{\otimes m} & \longrightarrow & 0 \\ \downarrow \cong & & \downarrow \cong & & & & \\ \bigoplus_{i=1}^m T[m-1] & \longrightarrow & T[m] & \longrightarrow & T \otimes_\Gamma L^{\otimes m} & \longrightarrow & 0 \end{array}$$

Thus $T \otimes_{\Gamma} L^{\otimes m} \cong cr(T)(\underline{m})$. Therefore $t^{\otimes n} \otimes_{\Gamma} L^{\otimes m} \cong cr(t^{\otimes n})(\underline{m}) = 0$ because $t^{\otimes n}$ is of degree n . Therefore the tensor products $\theta^n \otimes_{\Gamma} F_{i,j}$ vanish if $i + j = m \neq n$. The case which is left to consider is $m = n$. In this case

$$\theta^m \otimes_{\Gamma} F_{i,j} \cong (\mathbb{K} \otimes cr(F_{i,j})(\underline{m})) / (f^*(x) \otimes y \sim x \otimes f_*(y)) \cong \mathbb{K} \otimes_{\Sigma_m} cr(F_{i,j})(\underline{m}).$$

Hence this cross-effect gives the coinvariants of the Σ_m -module $cr(\Lambda^i \circ L \otimes \text{Sym}^j \circ L)(\underline{m})$. As $F_{i,j}$ is a quotient of $L^{\otimes m}$ and as taking cross effects is exact, we get

$$cr(L^{\otimes m}) \twoheadrightarrow cr(F_{i,j}) \quad (*)$$

Lemma 6.2 *As a Σ_m -module $cr_m(L^{\otimes m})$ is isomorphic to $\mathbb{K}[\Sigma_m]$.*

Proof By definition $L^{\otimes m}([n])$ is the free vector space generated by all m -tuples of elements in $\{1, \dots, n\}$. The kernel of the map $L^{\otimes m}(r_i) : L^{\otimes m}([n]) \rightarrow L^{\otimes m}([n-1])$ consists of all m -tuples which contain i , because $L^{\otimes m}(r_i)((x_1, \dots, x_m)) = (r_i(x_1), \dots, r_i(x_m))$. Hence the intersection of all of these kernels are the m -tuples which contain each $i \in \{1, \dots, m\}$ exactly once. \square

Thus the sequence $(*)$ reduces to $\mathbb{K}[\Sigma_m] \twoheadrightarrow cr_m(F_{i,j})$. Taking coinvariants shows that the coinvariants of $cr_m(F_{i,j})$ are isomorphic to \mathbb{K} or to 0 , because $\mathbb{K} \twoheadrightarrow \mathbb{K} \otimes_{\Sigma_m} cr_m(F_{i,j})$. This statement can be made more precise:

Lemma 6.3

$$\mathbb{K} \otimes_{\Sigma_m} cr_m(F_{i,j}) \cong \begin{cases} \mathbb{K} & i = 0, 1 \\ 0 & \text{else.} \end{cases}$$

Proof Let $\pi_1 : L^{\otimes i} \rightarrow \Lambda^i \circ L$ and $\pi_2 : L^{\otimes j} \rightarrow \text{Sym}^j \circ L$ be the canonical maps. The natural transformation $L^{\otimes m} \xrightarrow{\pi_1 \otimes \pi_2} F_{i,j}$ gives a map on the corresponding cross effects by restriction. But for $i > 1$ the we get $\pi_1 \otimes \pi_2(x_1, \dots, x_m) = x_1 \wedge \dots \wedge x_i \otimes x_{i+1} \cdots x_m$. Taking coinvariants this term is equivalent to its negative and hence it vanishes. \square

This finishes the proof of our proposition and leads to the calculation of the Koszul resolutions: Applying our results there are only two nontrivial sequences, namely $0 \rightarrow \theta^n \otimes_{\Gamma} (\Lambda^1 \otimes \text{Sym}^{(n+1)-2}) \circ L \rightarrow \theta^n \otimes_{\Gamma} \text{Sym}^{n+1} \circ L \rightarrow \theta^n \otimes_{\Gamma} \psi_{n+1} \rightarrow 0$ which gives $0 \rightarrow \mathbb{K} \rightarrow 0 \rightarrow \theta^n \otimes_{\Gamma} \psi_{n+1} \rightarrow 0$ and $0 \rightarrow \mathbb{K} \rightarrow \theta^n \otimes_{\Gamma} \psi_n \rightarrow 0$ with the \mathbb{K} arising from $\theta^n \otimes_{\Gamma} \text{Sym}^n \circ L$. The corresponding Tor-groups are

$$\text{Tor}_{\ell}^{\Gamma}(\theta^n, \psi_m) = \begin{cases} \mathbb{K} & \ell = 0 \quad m = n \\ \mathbb{K} & \ell = 1 \quad m = n + 1 \\ 0 & \text{else.} \end{cases}$$

6.1 Application to higher order Hochschild homology

In this section the ground ring \mathbb{K} is a field of characteristic zero. For a commutative \mathbb{K} -algebra A and an A -module M let $\mathcal{L}(A, M)$ be the Γ -module which sends a finite pointed set $[n]$ to $M \otimes A^{\otimes n}$. A morphism $f : [n] \rightarrow [m]$ in Γ maps an element $a_0 \otimes \cdots \otimes a_n$ in $M \otimes A^{\otimes n}$ to $b_0 \otimes \cdots \otimes b_m$ with $b_i = \prod_{f(j)=i} a_j$. Hochschild homology of order d is defined via the evaluation on the simplicial d -sphere

$$H_*^{[d]}(A, M) := \pi_*(\mathcal{L}(A, M)(\mathbb{S}^d)).$$

As a concrete example we will calculate $H_*^{[d]}(\mathbb{K}[x]/x^2, \mathbb{K})$ for d even. For d odd the calculation of $H_*^{[d]}(\mathbb{K}[x]/x^2, \mathbb{K}[x]/x^2)$ is done in [P3], 5.4.

As it is shown in 1.8 of [P3] there is a splitting

$$\mathcal{L}(\mathbb{K}[x]/x^2, \mathbb{K}) \cong \bigoplus_k \psi_k$$

which leads to a decomposition

$$H_n^{[d]}(\mathbb{K}[x]/x^2, \mathbb{K}) \cong \bigoplus_{i+dj=n} \bigoplus_k \mathrm{Tor}_i(\theta^j, \psi_k)$$

for d even. Hence the calculation reduces to the determination of the Tor -groups which we have just calculated. Thus we proved the following

Theorem 6.4 *For d even the Hochschild homology of order d of $\mathbb{K}[x]/x^2$ with coefficients in \mathbb{K} is*

$$H_n^{[d]}(\mathbb{K}[x]/x^2; \mathbb{K}) \cong \bigoplus_{i+dj=n} \bigoplus_k \mathrm{Tor}_i^\Gamma(\theta^j, \psi_k) \cong \begin{cases} \mathbb{K} & \text{if } d|n \\ \mathbb{K} & \text{if } d|n - 1 \\ 0 & \text{else} \end{cases}$$

7 A spectral sequence for $H_* D_n F[1]$

We saw that the homology of the homotopy fibre $D_n F_*[1] = \mathbf{cone}_{*+1}(P_n F \rightarrow P_{n-1} F)[1]$ is determined by $\mathrm{Tor}_*^\Gamma(\theta^n, F)$. In [P2] Pirashvili developed a hyperhomology spectral sequence with abutment $\mathrm{Tor}_*^\Gamma(t, F)$. A generalization of this approach leads to a spectral sequence which converges to $\mathrm{Tor}_*^\Gamma(\theta^n, F)$. In the following part let k be a field.

7.1 Iterated partitions

For the definition of the spectral sequence we need the notion of iterated partitions. The term *p-partition* is defined inductively. A 1-partition (or simply partition) of some natural number m is a sequence $\lambda = (\lambda_1, \dots, \lambda_\ell)$ with $\ell \geq 1$ and $1 \leq \lambda_1 \leq \dots \leq \lambda_\ell$ where the λ_i add up to $m = \lambda_1 + \dots + \lambda_\ell$. Here ℓ is called the length of the partition λ and is denoted by $\ell(\lambda)$. For $n \geq 2$ an *n-partition* is a partition $\lambda = (\lambda_1, \dots, \lambda_j)$ together with $(n - 1)$ -partitions λ^i of λ_i for $1 \leq i \leq j$. The length of an *n-partition* is an *n-tuple* of natural numbers

$$\ell(\lambda) = (\ell(\lambda^1) + \dots + \ell(\lambda^j), j)$$

The set of *p-partitions* of n_0 with length (n_1, \dots, n_{p-1}, n) is denoted by $\Pi(n_0, \dots, n_{p-1}, n)$. For instance a λ in $\Pi(7, 5, 3, 2)$ can be the following:

$$\begin{array}{cccc} \cdot & \cdot & \cdot & \cdot \\ \cdot & \text{---} & \cdot & \cdot & \text{---} & ((1,2),(1,1,2)) \\ \cdot & \text{---} & \text{---} & \text{---} & & ((1,2), 4) \\ \text{---} & & \text{---} & & & (3,4) \end{array}$$

The partition $(3, 4)$ of 7 is refined taking the partition of 3 into $(1, 2)$ and the partition of 4 into $(1, 1, 2)$.

We associate to any *n-partition* a group of permutations: A 1-partition $\lambda = (\lambda_1, \dots, \lambda_\ell)$ yields the group $\Sigma_\lambda = \Sigma_{\lambda_1} \times \dots \times \Sigma_{\lambda_\ell}$ and to an *n-partition* $\mu = (\mu^1, \dots, \mu^j)$ we associate iteratively the group $\Sigma_\mu = \Sigma_{\mu^1} \times \dots \times \Sigma_{\mu^j}$. In the example above we obtain $\Sigma_\lambda = \Sigma_1 \times \Sigma_2 \times \Sigma_1 \times \Sigma_1 \times \Sigma_2 \cong \Sigma_2 \times \Sigma_2$.

7.2 The spectral sequence

In the following we will outline the construction of the hyperhomology spectral sequence. All functors F will have values in k -vector spaces.

Theorem 7.1 *There is a spectral sequence $E_{p,q}^1 \implies \text{Tor}_{p+q}^\Gamma(\theta^m, F)$ of the following form:*

$$E_{pq}^1 = \bigoplus_{\substack{n_0 > \dots > n_{p-1} > n \\ \lambda \in \Pi(n_0, \dots, n_{p-1}, n)}} H_q(\Sigma_\lambda, cr(F)(\underline{n}_0)).$$

Remark 7.2 *If we work over $k = \mathbb{Q}$ then this spectral sequence just consists of the zeroth row.*

7.3 A chain complex of right Ω -modules

Using the Dold-Kan correspondence between Γ -modules and Ω -modules, we can work in the category of Ω -modules to calculate $\mathrm{Tor}_*^\Gamma(\theta^n, F)$. The following result relates these derived functors with Tor -groups for Ω -modules.

Proposition 7.3 *For Γ -modules there is an isomorphism*

$$\mathrm{Tor}_*^\Gamma(T, F) \cong \mathrm{Tor}_*^\Omega(\mathrm{cr}(T), \mathrm{cr}(F)).$$

We will only indicate how the proof works. One uses that the equivalence cr maps the family of reduced projective generators $(L^{\otimes m})_m$ to the family of representable functors in the category of Ω -modules. The Yoneda lemma implies that the assumption holds for these generators. A full proof is given in [R, Prop. 2.5.1].

An El -category is a small category with all endomorphisms being automorphisms; Ω is an El -category with the permutation groups Σ_n as endomorphisms of \underline{n} . In such a situation there is a standard resolution $\mathcal{K}_*(U)$ of every $U : \Omega^{op} \rightarrow k\text{-Vect}$ (as in [P2, 4.3] or [L]). With $\Omega(\underline{n}, \underline{m})$ we denote the morphisms in Ω from \underline{n} to \underline{m} . This set has a canonical right Σ_n and a left Σ_m action. In degree ℓ the chain complex of right Ω -modules $\mathcal{K}_*(U)$ looks as follows

$$\mathcal{K}_\ell(U)(-) :=$$

$$\bigoplus U(\underline{n}_\ell) \otimes_{\Sigma_{n_\ell}} k \{ \Omega(\underline{n}_{\ell-1}, n_\ell) \} \otimes_{\Sigma_{n_{\ell-1}}} \cdots \otimes_{\Sigma_{n_1}} k \{ \Omega(\underline{n}_0, n_1) \} \otimes_{\Sigma_{n_0}} k \{ \Omega(-, n_0) \}$$

where the sum runs over all $n_0 > \dots > n_\ell$.

The boundary map d on an element $(a; f_\ell, \dots, f_0)$ with $a \in U(\underline{n}_\ell)$ is defined as

$$\begin{aligned} d(a; f_\ell, \dots, f_0) &= \sum_{i=0}^{\ell-1} (-1)^i (a; f_\ell, \dots, f_{i+1} f_i, \dots, f_0) + (-1)^\ell (f_\ell^*(a); f_{\ell-1}, \dots, f_0) \end{aligned}$$

A proof that this complex is a resolution of U can be found in [P2, Lemma 4.4], hence for every Ω -module F we obtain a hyperhomology spectral sequence

$$E_{pq}^1 = \mathrm{Tor}_q^\Omega(\mathcal{K}_p(U), F) \Rightarrow \mathrm{Tor}_{p+q}^\Omega(U, F).$$

7.4 Simplification of the spectral sequence for $U = \theta^n$

For $\theta^n : \Gamma^{op} \rightarrow k\text{-Vect}$ and $F : \Gamma \rightarrow k\text{-Vect}$, the above spectral sequence gives

$$E_{pq}^1 = \text{Tor}_q^\Omega(\mathcal{K}_p(cr(\theta^n)), cr(F)) \Rightarrow \text{Tor}_{p+q}^\Omega(cr(\theta^n), cr(F)) \cong \text{Tor}_{p+q}^\Gamma(\theta^n, F).$$

But we know that $cr(\theta^n)(\underline{i}) = 0$ if $i \neq n$. Hence the above chain complex reduces to

$$\mathcal{K}_\ell(U) =$$

$$\bigoplus k \otimes_{\Sigma_n} k \{ \Omega(\underline{n}_{\ell-1}, \underline{n}) \} \otimes_{\Sigma_{n_{\ell-1}}} \cdots \otimes_{\Sigma_{n_1}} k \{ \Omega(\underline{n}_0, \underline{n}_1) \} \otimes_{\Sigma_{n_0}} k \{ \Omega(-, \underline{n}_0) \}$$

Here the sum is taken over all $n_0 > \dots > n_{\ell-1} > n$. According to lemma 4.6 in [P2] we obtain

$$\text{Tor}_*^\Omega(M \otimes_{\Sigma_n} k \{ \Omega(-, \underline{n}) \}, T) \cong \text{Tor}_*^{\Sigma_n}(M, T(\underline{n}))$$

for all Σ_n -modules M and all Ω -modules T .

We gain an even stronger simplification by applying lemma 4.8 in [P2]: The Σ_n -module

$$k \otimes_{\Sigma_n} k \{ \Omega(\underline{n}_{p-1}, \underline{n}) \} \otimes_{\Sigma_{n_{p-1}}} \cdots \otimes_{\Sigma_{n_1}} k \{ \Omega(\underline{n}_0, \underline{n}_1) \}$$

is isomorphic to

$$\bigoplus_{\lambda \in \Pi(n_0, \dots, n)} k [\Sigma_{n_0} / \Sigma_\lambda].$$

After all these reductions our spectral sequence looks as follows:

$$E_{pq}^1 = \text{Tor}_q^\Omega(\mathcal{K}_p(cr(\theta^n)), cr(F)) = \bigoplus_{\substack{n_0 > \dots > n_{p-1} > n \\ \lambda \in \Pi(n_0, \dots, n_{p-1}, n)}} \text{Tor}_q^{\Sigma_{n_0}}(k[\Sigma_{n_0} / \Sigma_\lambda]; (cr(F))(\underline{n}_0))$$

Using the Shapiro lemma in group homology we obtain

$$\begin{aligned} \text{Tor}_q^{\Sigma_{n_0}}(k[\Sigma_{n_0} / \Sigma_\lambda]; cr(F)(\underline{n}_0)) &\cong \text{Tor}_q^{\Sigma_{n_0}}(k; k[\Sigma_{n_0} / \Sigma_\lambda] \otimes cr(F)(\underline{n}_0)) \\ &\cong H_q(\Sigma_{n_0}, \Sigma_{n_0} / \Sigma_\lambda \otimes cr(F)(\underline{n}_0)) \\ &\cong H_q(\Sigma_\lambda, cr(F)(\underline{n}_0)) \end{aligned}$$

Therefore the final version of our spectral sequence for the homology of the n -th homotopy fibre $\text{Tor}_*^\Gamma(\theta^n, F)$ is

$$E_{pq}^1 = \bigoplus_{\substack{n_0 > \dots > n_{p-1} > n \\ \lambda \in \Pi(n_0, \dots, n_{p-1}, n)}} H_q(\Sigma_\lambda, cr(F)(\underline{n}_0)).$$

Remark 7.4 *Note that the $E_{0,q}^1$ -term for $\mathrm{Tor}(\theta^n, \psi_m)$ consists of $\mathrm{Tor}_q(k \otimes_{\Sigma_n} \Omega_n, cr(\psi_m)) \cong \mathrm{Tor}_q^{\Sigma_n}(k, cr(\psi_m)(\underline{n})) \cong \mathrm{Tor}_q^{\Sigma_n}(k, k)$ iff $m = n$. Otherwise this term is trivial.*

8 The dual of the Steenrod algebra

8.1 Decomposition as a Γ -vector space

As an example for an explicit calculation we will consider the functor

$$\begin{aligned} St : \Gamma &\longrightarrow \mathbb{F}_2\text{-Vect} \\ [n] &\mapsto \mathbb{F}_2 \{ \overline{\mathbb{F}_2} \{ [n] \} \} \end{aligned}$$

from finite pointed sets to \mathbb{F}_2 -vector spaces, which takes a finite pointed set to the reduced vector space on the elements and takes then the free \mathbb{F}_2 -vector space of this. Prolonging this functor to simplicial pointed sets and evaluating it on an arbitrary simplicial model for a sphere leads to the homology of Eilenberg-MacLane spaces. As $\pi_*^{st}(St) \cong \mathrm{Tor}_*^\Gamma(t, St)$ (see [P3, Prop 2.2]), we gain that the homology of the first approximation evaluated at [1] is nothing but the dual of the Steenrod algebra.

Recall that we denote by $\mathcal{B}_\ell : \Gamma \rightarrow \mathbb{F}_2\text{-Vect}$ the functor that maps a finite pointed set S_+ to the free \mathbb{F}_2 -vector space which is generated by all nonempty subsets of S with cardinality less or equal to ℓ and that we abbreviate the functor $\mathcal{B}_\ell/\mathcal{B}_{\ell-1}$ by ψ_ℓ .

For our calculations the whole functor St would be too complicated to deal with, but we can show that this functor splits into homogenous pieces, namely St is a sum of the functors ψ_ℓ which are easier to handle.

Theorem 8.1 *As a Γ -module St splits into*

$$St \cong \bigoplus_{\ell \geq 0} \psi_\ell,$$

where ψ_0 is the constant functor with value \mathbb{F}_2 on every object.

We will prove that $cr(St)$ is a split functor in the category of Ω -modules. Let St_n abbreviate $cr_n St([1], \dots, [1])$.

Proposition 8.2 *Every map $f : \underline{n} \rightarrow \underline{n-1}$ in Ω induces the trivial map $f_* : St_n \rightarrow St_{n-1}$.*

Lemma 8.3 *All vector spaces St_n are of dimension one*

$$\dim_{\mathbb{F}_2} St_n = 1.$$

Proof We will prove $cr_n St([1], \dots, [1]) \cong \mathbb{F}_2$ and $cr_n St([1], \dots, [1], [k]) \cong \mathbb{F}_2^{2^k - 1}$ inductively. In degree one we have that

$$St[0] \oplus cr_1 St[1] = St[1] = \mathbb{F}_2 [\overline{\mathbb{F}_2}[1]],$$

hence $cr_1 St[1] \cong \mathbb{F}_2$ and

$$St[k] = St[0] \oplus cr_1 St[k] \cong \mathbb{F}_2^{2^k},$$

so $cr_1 St[k] \cong \mathbb{F}_2^{2^k - 1}$. Assume the two claims are true for all $i < n$. From the definition of the cross-effect of St and the assumption we gain

$$\begin{aligned} St_n &\cong cr_2(cr_{n-1} St([1], \dots, [1], _))([1], [1]) \\ &\cong \ker(cr_{n-1} St([1], \dots, [1], [2]) \rightarrow St_{n-1} \times St_{n-1}) \\ &\cong \ker(\mathbb{F}_2^3 \rightarrow \mathbb{F}_2 \times \mathbb{F}_2) \\ &\cong \mathbb{F}_2 \end{aligned}$$

The last isomorphism comes from the fact that the map from \mathbb{F}_2^3 to $\mathbb{F}_2 \times \mathbb{F}_2$ is surjective. The second claim is also straightforward to see:

$$\begin{aligned} cr_n St([1], \dots, [k]) &\cong \ker(cr_{n-1} St([1], \dots, [1], [k+1]) \\ &\quad \rightarrow St_{n-1} \times cr_{n-1} St([1], \dots, [1], [k])) \\ &\cong \ker(\mathbb{F}_2^{2^{k+1}-1} \rightarrow \mathbb{F}_2 \times \mathbb{F}_2^{2^k-1}) \\ &\cong \mathbb{F}_2^{2^k-1} \end{aligned}$$

and hence the proof is completed. \square

Proof of the proposition As St_n is one dimensional we have only to prove that the basis element is mapped trivially to St_{n-1} . Let e_1, \dots, e_n denote the canonical basis of $\overline{\mathbb{F}_2}[n]$. Then we claim that the element

$$E_n := (e_1 + \dots + e_n) + \sum_{i=1}^n (e_1 + \dots + \check{e}_i \dots + e_n) + \dots + (e_1) + \dots + (e_n)$$

is a basis of St_n . Here the inner sums are taken in $\mathbb{F}_2\{\underline{n}\}$ whereas the sums outside of the parenthesis are taken in $\mathbb{F}_2\{\overline{\mathbb{F}_2}\{-}\}$. We have to prove that E_n is in the intersections of the kernels of the $St(r_i)$. Since E_n is symmetric

with respect to the action of the symmetric group, it is enough to show that $St(r_n)(E_n) = 0$. Let $(E_{n-1} + e_n)$ denote the sum over all summands in E_n which contain e_n and some term from E_{n-1} . It is obvious that we can decompose E_n in

$$E_n = (E_{n-1} + e_n) + E_{n-1} + (e_n)$$

But then it is easy to see that $St(r_n)(E_n) = E_{n-1} + E_{n-1} = 0$.

Now let $f : \underline{n} \rightarrow \underline{n-1}$ be a map in Ω . Without loss of generality we can assume that $f(n) = f(n-1) = n-1$. But then $f_*(E_n) = 2E_{n-1} = 0$.

As $cr(St)$ and $\bigoplus cr(\psi_i)$ have the same values on objects and as they have only trivial transformations, they coincide. Using the Dold-Kan correspondence between Γ -modules and Ω -modules we obtain a splitting for St . \square

As a concrete example we will calculate the homology of the homotopy fibre of the quadratic approximation of the functors ψ_ℓ , for $\ell = 2, 3, 4$ over some field k .

8.1.1 $\mathrm{Tor}_*^\Gamma(\theta^2, \psi_\ell)$, $\ell = 2, 3, 4$

a) From remark 7.4 we see that $\mathrm{Tor}_q^\Gamma(\theta^2, \psi_2) \cong H_q(\Sigma_2; k)$.

b) $\mathrm{Tor}_*^\Gamma(\theta^2, \psi_3)$

The hyperhomology spectral sequence for $\mathrm{Tor}_*^\Gamma(\theta^2, \psi_3)$ is

$$E_{pq}^1 = \bigoplus_{\substack{n_1 > \dots > n_p > 2 \\ \lambda \in \Pi(n_1, \dots, n_p, 2)}} H_q(\Sigma_\lambda; (cr(\psi_3))(\underline{n}_1))$$

But $cr(\psi_3)(\underline{n}) = 0$ unless $n = 3$. Having remark 7.4 in mind we see that the spectral sequence consists only of a nontrivial E_{1q}^1 part, namely

$$\begin{array}{cccc} \vdots & & \vdots & \vdots \\ 0 & \bigoplus_{\lambda \in \Pi(3,2)} H_1(\Sigma_\lambda; k) & 0 & \dots \\ 0 & \bigoplus_{\lambda \in \Pi(3,2)} H_0(\Sigma_\lambda; k) & 0 & \dots \end{array}$$

There is only one partition $\lambda \in \Pi(3, 2)$ namely $\lambda = (1, 2)$ and for this partition we have that $\Sigma_\lambda = \Sigma_1 \times \Sigma_2 \cong \Sigma_2$. All differentials are trivial in this case, hence we obtain for all n

$$\mathrm{Tor}_n^\Gamma(\theta^2, \psi_3) = E_{1,n-1}^1 = H_{n-1}(\Sigma_2; k).$$

c) $\text{Tor}_*^\Gamma(\theta^2, \psi_4)$

From now on all coefficients are taken in k without mentioning them anymore. In a similar manner as in the above case we obtain that the E^1 -term for $\text{Tor}_*^\Gamma(\theta^2, \psi_4)$ reduces to

$$E_{pq}^1 = \bigoplus_{\substack{n_1 > \dots > n_p > 2 \\ \lambda \in \Pi(n_1=4, \dots, n_p, 2)}} H_q(\Sigma_\lambda)$$

The resulting E^1 is

$$\begin{array}{c|c|c|c|c} \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & H_1(\Sigma_3) \oplus H_1(\Sigma_2 \times \Sigma_2) & 3H_1(\Sigma_2) & 0 & \dots \\ 0 & H_0(\Sigma_3) \oplus H_0(\Sigma_2 \times \Sigma_2) & 3H_0(\Sigma_2) & 0 & \dots \end{array}$$

The differentials arise from the differentials in the chain complex $\mathcal{K}_*(cr(\theta^2))$. Therefore one copy of $H_*(\Sigma_2)$ which corresponds to the 2-partition $(1, 3)$, $(1, 1, 2)$ is horizontally mapped to the summand $H_*(\Sigma_3)$. The boundary of the other summand which corresponds to the 2-partition $(2, 2)$, $(1, 1, 2)$ is mapped to $H_*(\Sigma_2 \times \Sigma_2)$. The E^2 -term that comes out is

$$\begin{array}{c|c|c|c} \vdots & \vdots & \vdots & \vdots \\ 0 & H_1(\Sigma_3)/H_1(\Sigma_2) \oplus H_1(\Sigma_2 \times \Sigma_2)/H_1(\Sigma_2) & H_1(\Sigma_2) & 0 \\ 0 & H_0(\Sigma_3)/H_0(\Sigma_2) \oplus H_0(\Sigma_2 \times \Sigma_2)/H_0(\Sigma_2) & H_0(\Sigma_2) & 0 \end{array}$$

Thus the next differential d^2 ends up in a zero column and hence $E^2 = E^\infty$ and

$$\begin{aligned} \text{Tor}_n^\Gamma(\theta^2, \psi_4) &\cong H_{n-2}(\Sigma_2; k) \oplus H_{n-1}(\Sigma_2 \times \Sigma_2; k)/H_{n-1}(\Sigma_2; k) \\ &\oplus H_{n-1}(\Sigma_3; k)/H_{n-1}(\Sigma_2; k) \end{aligned}$$

Remark 8.4 *In a similar manner one can use the spectral sequence to compute $\text{Tor}_*^\Gamma(\theta^n, \psi_m)$ for $m = n, n+1, n+2$.*

8.2 Homology of posets of partitions

We saw in section 6 how to compute $\text{Tor}(\theta^n, \psi_m)$ at least over the rational numbers. These Tor-groups have an interpretation as the homology of a poset of certain unordered partitions, namely those partitions arising as layers of

p -partitions. Let Ξ be a p -partition of n , i.e. Ξ is a partition $\lambda = (\lambda_1, \dots, \lambda_k)$ with $1 \leq \lambda_1 \leq \dots \leq \lambda_k$ and $\sum \lambda_i = n$ together with $(p-1)$ -partitions of the λ_i : $(\lambda_i^1, \dots, \lambda_i^{n_i})$. The collection $((\lambda_1^1, \dots, \lambda_1^{n_1}), \dots, (\lambda_k^1, \dots, \lambda_k^{n_k}))$ is no actual partition in general because it might happen that $\lambda_j^{n_j} \geq \lambda_{j+1}^1$.

Definition 8.5 *An ℓ -tuple $a = (a_1, \dots, a_\ell)$ of natural numbers is an unordered partition of n if $1 \leq a_i$ and $\sum a_i = n$. Then ℓ is called the length of a .*

In a p -partition, $(\lambda_1, \dots, \lambda_k)$ is called the first layer of the p -partition Ξ , the second layer is $((\lambda_1^1, \dots, \lambda_1^{n_1}), \dots, (\lambda_k^1, \dots, \lambda_k^{n_k}))$ and so on. Hence a p -partition Ξ consists of p layers of unordered partitions.

Definition 8.6 *An unordered partition λ of n is called grown if λ is a layer of some p -partition Ξ .*

Example The unordered partition $(1, 2, 1, 1, 2)$ is grown because it is a third layer of the 3-partition $(3, 4), (1, 2, 4)$ and $(1, 2, 1, 1, 2)$. A typical example for an unordered partition which is not grown is something of the form $(n, 1)$ with $n > 1$.

Definition 8.7 *Let μ and ν be two grown partitions. Then ν is a refinement of μ if there is a p -partition Ξ and ν is a higher layer of Ξ than μ .*

Let $\Pi(m, n)$ be the set of all grown partitions of m which arise from an actual partition of length n . We say that $\lambda < \mu$ for $\lambda, \mu \in \Pi(m, n)$, if λ is a refinement of μ . The homology of the poset $\Pi(m, n)$ can be described as follows:

Theorem 8.8

$$H_*(\Pi(m, n); \underline{\mathbb{Q}}) \cong \begin{cases} \mathbb{Q} & * = 0 & m = n \\ \mathbb{Q} & * = 1 & m = n + 1 \\ 0 & \text{else} \end{cases}$$

Here $\underline{\mathbb{Q}}$ is the constant functor, which assigns the field \mathbb{Q} to every unordered partition.

Proof The spectral sequences which converges to $\text{Tor}_*^\Gamma(\theta^n, \psi_m)$ degenerates at the E^2 -level over the rational numbers. The E^1 -term reduces to

$$E_{p,0}^1 = \bigoplus_{\substack{n_1=m > n_2 > \dots > n_p > n \\ \Xi \in \Pi(m, n_2, \dots, n_p, n)}} \mathbb{Q}$$

because the zeroth group homology of any symmetric group $H_0(\Sigma_\lambda, \mathbb{Q})$ is \mathbb{Q} . The first differential comes from the differential in $K_*(cr(\theta^n))$, hence it just forgets some layers. But this is exactly what the differential does in the complex which computes the homology of the poset $\Pi(m, n)$. A p -partition $\Xi \in \Pi(m, n_2, \dots, n_p, n)$ is nothing but a p -string of composable morphisms in $\Pi(m, n)$.

□

Remark 8.9 *From the proof of the theorem it is clear that for an arbitrary field k it is still true that the E^2 -term for $\text{Tor}_*^\Gamma(\theta^n, \psi_m)$ consists of the homology of the partition poset with coefficients in the functor which takes a partition to the homology of its corresponding symmetric group.*

$$E_{p,q}^2 \cong H_p(\Pi(m, n); H_q(\Sigma_{()}, k)).$$
