ARTICLE HISTORY
Compiled July 20, 2017

ABSTRACT
We study the disturbance decoupled estimation problem for linear differential-algebraic systems which are not necessarily regular. We introduce the notion of partial state observers following a recent approach to observer design motivated by considerations for behavioral systems. In our framework, a partial state observer is itself a differential-algebraic system. We derive a characterization for existence of (asymptotic) partial state observers. Exploiting the freedom in the proposed observer design, we derive a solution of the disturbance decoupled estimation problem. The characterization of solvability is obtained via geometric conditions in terms of the generalized Wong sequences.

KEYWORDS
Differential-algebraic systems; descriptor systems; disturbance decoupled estimation; observer design; Wong sequences

1. Introduction

We study linear time-invariant systems (the plant) given by differential-algebraic equations (DAEs) of the form

\[ \frac{d}{dt}Ex(t) = Ax(t) + Bu(t), \]

\[ y(t) = C_1x(t) + D_1u(t), \]

\[ z(t) = C_2x(t) + D_2u(t), \]

where \( E, A \in \mathbb{R}^{l \times n} \), \( B \in \mathbb{R}^{l \times m} \), \( C_i \in \mathbb{R}^{p_i \times n} \), \( D_i \in \mathbb{R}^{p_i \times m} \), \( i = 1, 2 \). Systems of that type are also called descriptor systems. The set of DAE systems (1) is denoted by \( \Sigma_{l,n,m,p_1,p_2} \) and we write \([E,A,B,C_1,C_2,D_1,D_2] \in \Sigma_{l,n,m,p_1,p_2} \). Systems of the form (1) occur when modeling dynamical systems subject to algebraic constraints; for a further motivation see Berger (2014); Brenan, Campbell, and Petzold (1989); Kunkel and Mehrmann (2006); Lamour, März, and Tischendorf (2013); Riaza (2008) and the references therein. In the present paper we do not assume that \( sE - A \) is regular, which would mean that \( l = n \) and \( \text{det}(sE - A) \in \mathbb{R}[s] \setminus \{0\} \).

The functions \( u : \mathbb{R} \rightarrow \mathbb{R}^m \), \( y : \mathbb{R} \rightarrow \mathbb{R}^{p_1} \) and \( z : \mathbb{R} \rightarrow \mathbb{R}^{p_2} \) are called input, measurement output and controlled output of the system (1), resp. The measurement output \( y \) contains those variables which can actually be obtained from measurements, e.g. via sensors, and the controlled output \( z \) contains those variables for which a desired behavior should be achieved (as an additional control task) and hence estimates are required for them. The outputs \( y \) and \( z \) do not
where a dynamical system whose input is composed of the input \( u \) and the measurement output \( y \) of the plant. The tuple \((x, u, y, z) : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^p \times \mathbb{R}^q \) is said to be a solution of (1), if it belongs to the behavior of (1):

\[
\mathcal{B}_{E,A,B,C_1,C_2,D_1,D_2} := \left\{ (x, u, y, z) \in L^1_{\text{loc}}(\mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^p \times \mathbb{R}^q) \mid \begin{array}{l} Ex \in \mathcal{A}_d(\mathbb{R} \to \mathbb{R}^l) \text{ and } (x, u, y, z) \text{ satisfies (1) for almost all } t \in \mathbb{R} \end{array} \right\}.
\]

DAE control systems based on the above behavior have been studied in detail e.g. in Berger (2014). For the analysis of DAE systems in \( \Sigma_{l,n,m,p_1,p_2} \), we assume that the states, inputs and outputs of the system are fixed a priori by the designer. This is different from other approaches based on the behavioral setting, see Berger and Van Dooren (2015); Campbell, Kunkel, and Mehrmann (2012).

Observer design for general differential-algebraic systems has been investigated recently in Berger and Reis (2015a). It is revealed that there is still a lot of freedom in the choice of the parameters which constitute an observer. This freedom may be exploited, for instance, for the construction of an observer such that the observation error does not depend on disturbances which might influence the plant. In the present paper we consider this so called disturbance decoupled estimation problem (DDEP) for differential-algebraic systems. To this end, we allow for disturbances of the plant (1), i.e., for given disturbance matrices \( Q_1 \in \mathbb{R}^{l\times q}, Q_2 \in \mathbb{R}^{p_1\times q}, Q_3 \in \mathbb{R}^{p_2\times q} \), we consider the system

\[
\Sigma : \begin{cases}
\frac{d}{dt} Ex(t) = Ax(t) + Bu(t) + Q_1 d(t), \\
y(t) = C_1 x(t) + D_1 u(t) + Q_2 d(t), \\
z(t) = C_2 x(t) + D_2 u(t) + Q_3 d(t),
\end{cases}
\]

where \( d \in \mathcal{C}_f(\mathbb{R} \to \mathbb{R}^q) \) represents a smooth disturbance, which may be induced by noise, modeling or measuring errors, or by higher terms in linearization. A (partial state) observer is a dynamical system whose input is composed of the input \( u \) and the measurement output \( y \) of the plant. The output of the to-be-built dynamical system will be a variable \( \hat{z} \) which approximates the controlled output \( z \) in a certain sense. We consider observers which are themselves DAEs given by

\[
\Sigma_{\text{obs}} : \begin{cases}
\frac{d}{dt} E_0 x_o(t) = A_o x_o(t) + B_o \begin{pmatrix} u(t) \\ y(t) \end{pmatrix}, \\
\hat{z}(t) = C_o x_o(t) + D_o \begin{pmatrix} u(t) \\ y(t) \end{pmatrix},
\end{cases}
\]

with \([E_o, A_o, B_o, C_o, 0, D_o, 0] \in \Sigma_{l_o,n_o,m+p_1,p_2} \); the situation is depicted in Figure 1. For brevity we set \( \Sigma_{l_o,n_o,m+p_1,p_2} := \Sigma_{l_o,n_o,m+p_1,p_2,0} \) and write \([E_o, A_o, B_o, C_o, D_o] \in \Sigma_{l_o,n_o,m+p_1,p_2} \) as well as \((x_0, (y, \hat{z})) \in \mathcal{B}_{[E_o, A_o, B_o, C_o, D_o]} \) for a solution of (3).

The idea of partial state observation goes back to Luenberger (1964, 1971), who showed that the state \( x \) of any linear system driven by the state \( w \) of a free linear system (i.e., \( u = 0 \)) is a linear combination of \( w \), i.e., \( x = Tw \) provided that \( x(0) = Tw(0) \) for some matrix \( T \). This idea has been picked up again in the context of disturbance decoupled estimation or, what is the same, unknown input observer design, see Bhattacharyya (1978); Hou and Müller (1992); Hou, Pugh, and Müller (1999); Kobayashi and Nakamizo (1982); this problem seems to have been first treated by Basile and Marro (1969a, 1969b). In contrast to this, the idea of designing observers for a pre-defined linear combination of the state, the controlled output, has been first
formulated in Akashi and Imai (1979); Schumacher (1980); Willems and Commault (1981) and the corresponding DDEP has been solved by Willems and Commault (1981). Another version, the *almost DDEP*, has been considered by Willems (1982). In practice, disturbance decoupled observers are important e.g. in the design of fault detection and isolation observers, see Hou and Müller (1994).

Observer design for DAE systems is the topic of recent (survey) articles by Berger and Reis (2015a); Bobinyec and Campbell (2014); Campbell (2015), see also the references therein. Partial state observers for DAEs have been first considered in Dai (1989), where they are called *Kx-observers* for the case $z = Kx$. The DDEP for DAEs using Luenberger observers in the case $z = x$ has been considered in Darouach, Zasadzinski, and Hayar (1996); Koenig and Mammar (2002); Paraskevopoulos, Koumboulis, Tzierakis, and Panagiotakis (1992); Yang and Tan (1989), where in Darouach et al. (1996); Paraskevopoulos et al. (1992); Yang and Tan (1989) $sE - A$ is required to be regular and in Koenig and Mammar (2002) also singular $sE - A$ is allowed. The DDEP with DAE observers of the form (3) has been treated in Chu and Mehrmann (1999); Dai (1989), where in Dai (1989) it is assumed that $sE - A$ and $sE_o - A_o$ are regular and $z = x$, and in Chu and Mehrmann (1999) it is assumed that both $sE - A$ and $sE_o - A_o$ are regular and of index at most one. In the present paper we consider the general setting.

The contribution of this paper is twofold. A rigorous definition of partial state observers is not available in the literature, not even for ODE systems, hence we introduce this concept following the behavioral approach as in Berger and Reis (2015a); Valcher and Willems (1999). Thereafter, we derive a characterization for existence of (asymptotic) partial state observers for DAE systems. The second contribution of this paper is the solution of the DDEP for DAEs. To this end, we introduce the notion of disturbance decoupled partial state observers and characterize existence. The aforementioned characterizations are completely geometric with which we follow the classical approach of geometric control theory, see e.g. the textbooks by Basile and Marro (1992); Trentelman, Stoorvogel, and Hautus (2001); Wonham (1985).

The present paper is organized as follows: In Section 2 we recall the generalized Wong sequences, which are the crucial geometric tool for the characterization of solvability of the DDEP. The notion of partial state observers for DAE systems is introduced and characterized in Section 3. In Section 4 we define when a partial state observer is called disturbance decoupled and show how feedthrough terms in the plant can be treated. Solvability of the DDEP for DAEs, i.e., existence of a disturbance decoupled partial state observer, is then characterized in Section 5. For completeness, we consider the problem of disturbance decoupled asymptotic estimation in Section 6.
In this section we introduce the crucial geometric tools for the solution of the DDEP. For the generalized Wong sequences

\[ \mathcal{W} \] the sequence

\[ \{ x \in \mathbb{R}^l \mid x \in \mathcal{S} \} \], the image of \( \mathcal{S} \subseteq \mathbb{R}^n \) under \( M \in \mathbb{R}^{l \times n} \)

\[ M^{-1} \mathcal{S} = \{ x \in \mathbb{R}^n \mid Mx \in \mathcal{S} \} \], the pre-image of the set \( \mathcal{S} \subseteq \mathbb{R}^l \) under \( M \in \mathbb{R}^{l \times n} \)

\( C^\infty (\mathbb{R} \to \mathbb{R}^n) \) the set of infinitely-times continuously differentiable functions \( f : \mathbb{R} \to \mathbb{R}^n \)

\( \mathcal{L}_1^1 (\mathbb{R} \to \mathbb{R}^n) \) the set of locally Lebesgue integrable functions \( f : \mathbb{R} \to \mathbb{R}^n \), where

\[ \int_K |f(t)| \, dt < \infty \quad \text{for all compact } K \subseteq \mathbb{R} \]

\( \mathcal{A} C (\mathbb{R} \to \mathbb{R}^n) \) the set of absolutely continuous functions \( f : \mathbb{R} \to \mathbb{R}^n \)

\( f \equiv g \) the functions \( f, g \in \mathcal{L}_1^1 (\mathbb{R}; \mathbb{R}^n) \) are equal “almost everywhere”, i.e., \( f(t) = g(t) \) for almost all (a.a.) \( t \in \mathbb{R} \)

\( \text{ess sup}_I \|f\| \) the essential supremum of the measurable function \( f : \mathbb{R} \to \mathbb{R}^n \) over \( I \subseteq \mathbb{R} \)

2. Generalized Wong sequences

In this section we introduce the crucial geometric tools for the solution of the DDEP. For \( E,A \in \mathbb{R}^{l \times n}, B \in \mathbb{R}^{l \times m}, C \in \mathbb{R}^{p \times n} \) we define the sequences

\[ \mathcal{W}_{i+1}^{(i)} [E,A,B,C] := A^{-1} \left( E \mathcal{W}_{i}^{(i)} [E,A,B,C] + \text{im}B \right) \cap \ker C, \quad i \geq 0, \]

\[ \mathcal{W}_{i+1}^{(i)} [E,A,B,C] := \{ 0 \}, \quad i \geq 0, \]

The sequence \( \mathcal{W}_{i}^{(i)} [E,A,B,C] \) is non-increasing and \( \mathcal{W}_{i}^{(i)} [E,A,B,C] \) is non-decreasing and both sequences terminate after finitely many steps, which justifies to define

\[ \mathcal{W}_{i}^{(i)} [E,A,B,C] := \bigcap_{i \in \mathbb{N}_0} \mathcal{W}_{i}^{(i)} [E,A,B,C], \quad \mathcal{W}_{i}^{(i)} [E,A,B,C] := \bigcup_{i \in \mathbb{N}_0} \mathcal{W}_{i}^{(i)} [E,A,B,C]. \]

We call the sequences \( \mathcal{W}_{i}^{(i)} [E,A,B,C] \) \( 0 \)-augmented Wong sequences, as introduced in Berger (2017). In Berger, Ilchmann, and Trenn (2012); Berger and Trenn (2012, 2013) the Wong sequences for matrix pencils (i.e., \( B = 0 \) and \( C = 0 \)) are investigated, the name chosen this way since Wong (1974) was the first who used both sequences for the analysis of matrix pencils. In Berger and Reis (2013, 2015b); Berger and Trenn (2014) the case \( C = 0 \) is considered and the sequences \( \mathcal{W}_{i}^{(i)} [E,A,0] \) and \( \mathcal{W}_{i}^{(i)} [E,A,0] \) are called \( 0 \)-augmented Wong sequences.
sequences. Similarly, in Berger, Reis, and Trenn (2017) the sequences \((\mathcal{W}_{[E,A,B,C]}^i)_{i \in \mathbb{N}_0}\) and
\((\mathcal{W}_{[E,A,0,C]}^i)_{i \in \mathbb{N}_0}\) (i.e., \(B = 0\)) are called restricted Wong sequences. For more details on these sequences see the surveys Berger and Reis (2013); Berger et al. (2017) and the references therein.

Note that in geometric control theory for ODE systems (i.e., \(E = I\)), see e.g. Wonham (1985), the sequence \((\mathcal{W}_{[I,A,B,C]}^i)_{i \in \mathbb{N}_0}\) is called invariant subspace algorithm, and the sequence \((\mathcal{W}_{[I,A,B,C]}^i)_{i \in \mathbb{N}_0}\) is called controllability subspace algorithm.

We need the following technical lemma.

Lemma 2.1. Let \(E, A \in \mathbb{R}^{l \times n}, B \in \mathbb{R}^{l \times m}, C_i \in \mathbb{R}^{n \times n}, i = 1, 2\). Then
\[
\mathcal{W}_{[E,0,0]}^i \subseteq \mathcal{W}_{[E,0]}^i \cap \mathcal{W}_{[E,0,0]}^i \subseteq \ker[C_2, 0] \iff \mathcal{W}_{[I,E,A,B,C]}^i \cap \mathcal{W}_{[I,E,A,B,C]}^i \subseteq \ker[C_2].
\]

Proof. For convenience we define, for \(i \in \mathbb{N}_0\),
\[
\hat{\mathcal{W}}_i := \mathcal{W}_{[E,0,0]}^i, \quad \mathcal{W}_i := \mathcal{W}_{[E,0]}^i, \quad \hat{\mathcal{W}}_i := \mathcal{W}_{[E,0,0]}^i, \quad \mathcal{W}_i := \mathcal{W}_{[E,A,B,C]}^i.
\]

Step 1: We show by induction that
\[
\forall i \in \mathbb{N}_0 : [I_n, 0] \hat{\mathcal{W}}_i = \mathcal{W}_i.
\]

For \(i = 0\) the statement is clearly true, so assume it is true for some \(i \in \mathbb{N}_0\). Then
\[
[I_n, 0] \hat{\mathcal{W}}_{i+1} = [I_n, 0] [A_{\frac{1}{2}}]^{-1} \left( [E_{\frac{1}{2}}] \hat{\mathcal{W}}_i \right)
= [I_n, 0] \left\{ (x_{\frac{1}{2}}) \in \mathbb{R}^n \times \mathbb{R}^m \mid A x_1 + B y_2 \in E[I_n, 0] \hat{\mathcal{W}}_i \wedge C_1 x_1 = 0 \right\}
= \left\{ x \in \mathbb{R}^n \mid \exists y \in \mathbb{R}^m, z \in \mathcal{W}_i : Ax = By + Ez \wedge C_1 x = 0 \right\}
= A^{-1}(E \mathcal{W}_i + \text{im} B) \cap \ker C_1 = \mathcal{W}_{i+1},
\]
which proves the assertion.

Step 2: For all \(i \geq 1\) we have that \(\hat{\mathcal{W}}_i = [I_n, 0] \hat{\mathcal{W}}_i \times \mathbb{R}^m\), which is immediate from
\[
\hat{\mathcal{W}}_i = [E_{\frac{1}{2}}]^{-1} \left( A_{\frac{1}{2}} \hat{\mathcal{W}}_{i-1} \right)
= \left\{ (x_{\frac{1}{2}}) \in \mathbb{R}^n \times \mathbb{R}^m \mid \exists y_{\frac{1}{2}} \in \mathcal{W}_{i-1} : E x_1 = A y_1 + B y_2 \wedge 0 = C_1 y_1 \right\}
= \left\{ (x_{\frac{1}{2}}) \in \mathbb{R}^n \times \mathbb{R}^m \mid x_1 \in [I_n, 0] \hat{\mathcal{W}}_i \right\}.
\]

Step 3: We show by induction that
\[
\forall i \in \mathbb{N}_0 : \mathcal{W}_i \subseteq [I_n, 0] \mathcal{W}_{i+1} \cap \ker C_1 \subseteq \mathcal{W}_{i+1}.
\]

For \(i = 0\) we have
\[
\mathcal{W}_0 = \{0\}, \quad [I_n, 0] \hat{\mathcal{W}}_1 = \ker E \cap \ker C_1, \quad \mathcal{W}_1 = E^{-1}(\text{im} B) \cap \ker C_1,
\]
and thus the assertion is true in this case. So we assume that it is true for some \( i \in \mathbb{N}_0 \). Then

\[
[I_n, 0] \mathcal{W}_{i+2} \cap \ker C_1 \\
= [I_n, 0] \left[ \begin{bmatrix} E & 0 \\ 0 & 0 \end{bmatrix} \right]^{-1} \left( \begin{bmatrix} A & B \\ C_1 & 0 \end{bmatrix} \mathcal{W}_{i+1} \right) \cap \ker C_1
\]

Step 2: Let \( \left\{ \begin{bmatrix} x_i \\ x_{i+1} \end{bmatrix} \right\} \in \mathbb{R}^n \times \mathbb{R}^m | \quad EX_i \in A([I_n, 0]\mathcal{W}_{i+1} \cap \ker C_1) + \text{im} B \} \cap \ker C_1
\]

\[
= E^{-1} \left( A([I_n, 0] \mathcal{W}_{i+1} \cap \ker C_1) + \text{im} B \right) \cap \ker C_1
\]

\[
\supseteq E^{-1} \left( A \mathcal{W}_i + \text{im} B \right) \cap \ker C_1 = \mathcal{W}_{i+1}.
\]

and analogously, just using the opposite inclusion in the line above, we obtain \([I_n, 0] \mathcal{W}_{i+2} \cap \ker C_1 \subseteq \mathcal{W}_{i+2}\).

Step 4: We show the statement of the lemma. It follows from Step 1 and Step 3 that

\[
\mathcal{Y}_{[E, A, B, C_1]}^\ast = [I_n, 0] \mathcal{Y}_{[E, A, B, C_1]}^\ast \cap \ker C_1,
\]

Since \( \mathcal{Y}_{[E, A, B, C_1]}^\ast \subseteq \ker C_1 \) we have

\[
\mathcal{Y}_{[E, A, B, C_1]}^\ast \cap \mathcal{Y}_{[E, A, B, C_1]}^\ast = [I_n, 0] \left[ \begin{bmatrix} E & 0 \\ 0 & 0 \end{bmatrix} \cdot \begin{bmatrix} A & B \\ C_1 & 0 \end{bmatrix}, 0, 0 \right] \cap \left[ I_n, 0 \right] \left[ \begin{bmatrix} E & 0 \\ 0 & 0 \end{bmatrix} \cdot \begin{bmatrix} A & B \\ C_1 & 0 \end{bmatrix}, 0, 0 \right].
\]

This already implies \( \Leftarrow \) in the statement of the lemma. To show \( \Rightarrow \) let \( x \in \mathcal{Y}_{[E, A, B, C_1]}^\ast \cap \mathcal{Y}_{[E, A, B, C_1]}^\ast \). Then there exists \( y \in \mathbb{R}^m \) such that \( \left( \begin{bmatrix} y \\ 0 \end{bmatrix} \right) \in \mathcal{Y}_{[E, A, B, C_1]}^\ast \). Furthermore, \( x \in [I_n, 0] \mathcal{Y}_{[E, A, B, C_1]}^\ast \) and by Step 2 it follows \( \left( \begin{bmatrix} y \\ 0 \end{bmatrix} \right) \in \mathcal{Y}_{[E, A, B, C_1]}^\ast \), hence \( x \in \ker C_2 \) which concludes the proof.

In order to consider (generalized) eigenspaces of a DAE we need to introduce the following modification of the second Wong sequence. As in Berger et al. (2012): Berger and Reis (2015b); Berger and Trenn (2013), for \( E, A \in \mathbb{R}^{l \times n} \) and \( \lambda \in \mathbb{C} \) we define the sequence of complex subspaces

\[
\mathcal{W}_{[E, A], \lambda}^0 := \{0\}, \quad \mathcal{W}_{[E, A], \lambda}^{i+1} := (A - \lambda E)^{-1} (E \mathcal{W}_{[E, A], \lambda}^i), \quad i \geq 0.
\]

This sequence is non-decreasing and terminates after finitely many steps, hence we may set

\[
\mathcal{W}_{[E, A], \lambda}^\ast := \bigcup_{i \in \mathbb{N}_0} \mathcal{W}_{[E, A], \lambda}^i.
\]

It is a straightforward calculation, see also Berger and Trenn (2013), that

\[
\text{span}_\mathbb{C} \left( \mathcal{Y}_{[E, A, 0, 0]}^\ast \cap \mathcal{Y}_{[E, A, 0, 0]}^\ast \right) \subseteq \mathcal{W}_{[E, A], \lambda}^\ast
\]

for all \( \lambda \in \mathbb{C} \), where \( \text{span}_\mathbb{C} (\mathcal{Y}) \) denotes the complex span of all the vectors in \( \mathcal{Y} \).
3. Partial state observers

In this section we introduce the concept of (asymptotic) partial state observers for DAE systems and derive characterizations for their existence. A partial state observer is a dynamical system which aims to reconstruct the controlled output. It should be able to process the signals of the plant without influencing the plant itself. This is subject of the following definition which follows the approach in Berger and Reis (2015a); Valcher and Willems (1999).

**Definition 3.1** (Acceptor). Consider a system \([E,A,B,C_1,C_2,D_1,D_2] \in \Sigma_{i,n,m,p_1,p_2}\). Then \([E_o,A_o,B_o,C_o,D_o] \in \Sigma_{i,n,o,m+p_1,p_2}\) is called an acceptor for \([E,A,B,C_1,C_2,D_1,D_2]\), if for all \((x,u,y,z) \in \mathcal{B}_{E,A,B,C_1,C_2,D_1,D_2}\), there exist \(x_0 \in \mathcal{L}^1_{\text{loc}}(\mathbb{R} \to \mathbb{R}^{n_o})\), \(\hat{z} \in \mathcal{L}^1_{\text{loc}}(\mathbb{R} \to \mathbb{R}^{p_o})\) such that

\[
(x_0,(y),\hat{z}) \in \mathcal{B}_{E_o,A_o,B_o,C_o,D_o}.
\]

The above definition means that there is a one-directed signal flow from the plant to its acceptor via input and measurement output, see Figure 2. That is, \([E,A,B,C_1,C_2,D_1,D_2]\) may influence \([E_o,A_o,B_o,C_o,D_o]\) but not vice-versa.

![Figure 2.: Interconnection with an acceptor](image)

The following definition of a partial state observer is a modification of the observer definition in Berger and Reis (2015a).

**Definition 3.2** (Partial state observer). Consider a system \([E,A,B,C_1,C_2,D_1,D_2] \in \Sigma_{i,n,m,p_1,p_2}\). Then \([E_o,A_o,B_o,C_o,D_o] \in \Sigma_{i,n,o,m+p_1,p_2}\) is called

a) a **partial state observer** for \([E,A,B,C_1,C_2,D_1,D_2]\), if it is an acceptor for \([E,A,B,C_1,C_2,D_1,D_2]\), and

\[
\forall (x,u,y,z,x_o,\hat{z}) \in \mathcal{L}^1_{\text{loc}}(\mathbb{R} \to \mathbb{R}^{n} \times \mathbb{R}^{n} \times \mathbb{R}^{p_1} \times \mathbb{R}^{p_2} \times \mathbb{R}^{n_o} \times \mathbb{R}^{p_o}) : \\
(x,u,y,z) \in \mathcal{B}_{E,A,B,C_1,C_2,D_1,D_2} \land (x_o,(y),\hat{z}) \in \mathcal{B}_{E_o,A_o,B_o,C_o,D_o} \\
\land \hat{z}(0) = z(0) \\
\Rightarrow \hat{z} \equiv z.
\]

b) an **asymptotic partial state observer** for \([E,A,B,C_1,C_2,D_1,D_2]\), if it is a partial state ob-
where \( \hat{\text{form}} (3) \) with what we would have expected to observe”. As depicted in (5), the partial state observer consists of an internal model of the plant driven by innovations “express how far the actual observed output differs from the prediction of the model.”

Partial state observers have been discussed in Bhattacharyya (1978); Hou et al. (1999); Kobayashi and Nakamizo (1982); Willems and Commault (1981) for ODE systems and in Chu and Mehrmann (1999); Dai (1989) for DAE systems. However, mostly observers of Luenberger type are considered and a characterization of existence of partial state observers of the form (3) is still not available in the literature. This is the topic of the remainder of this section.

We propose a partial state observer similar to the observer design introduced in Berger and Reis (2015a). Given a plant \([E,A,B,C_1,C_2,D_1,D_2] \in \Sigma_{l,m,n,p_1,p_2}\), let \(k \in \mathbb{N}_0\), \(L_x \in \mathbb{R}^{n \times k}\), \(L_y \in \mathbb{R}^{p_1 \times k}\) and \(L_z \in \mathbb{R}^{p_2 \times k}\), and consider the following observer design,

\[
\begin{align*}
\frac{dx}{dt} &= A x_o(t) + Bu(t) + \xi(t), \\
y(t) &= C_1 x_o(t) + D_1 u(t) + \eta(t), \\
\hat{z}(t) &= C_2 x_o(t) + D_2 u(t) + \omega(t),
\end{align*}
\]

where \(\hat{z}\) is the observer output. In other words, we consider a partial state observer of the form (3) with

\[
[E_o,A_o,B_o,C_o,D_o] = \begin{bmatrix} E & 0 & L_x \\ 0 & A & C_1 \\ 0 & C_1 & -I \end{bmatrix}, \quad \begin{bmatrix} B \\ D_1 \\ D_2 \end{bmatrix}
\]

As depicted in (5), the partial state observer consists of an internal model of the plant driven by innovations. This design goes back to Polderman and Willems (Polderman & Willems, 1998, p. 351) and the innovations “express how far the actual observed output differs from what we would have expected to observe”.

The interconnection of \([E,A,B,C_1,C_2,D_1,D_2]\) and \([E_o,A_o,B_o,C_o,D_o]\), as depicted in Figure 2, is described by the control system

\[
\begin{bmatrix} E & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & E & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ x_o(t) \\ w(t) \\ \end{bmatrix} = \begin{bmatrix} A & 0 & 0 & 0 \\ C_1 & -I & 0 & 0 \\ 0 & 0 & A & L_x \\ 0 & -I & C_1 & L_y \\ \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ x_o(t) \\ w(t) \\ \end{bmatrix} + \begin{bmatrix} B \\ D_1 \\ D_2 \\ \end{bmatrix} u(t).
\]

Introducing the difference \(v(t) = x_o(t) - x(t)\) we obtain

\[
\begin{bmatrix} E & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & E & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ v(t) \\ w(t) \\ \end{bmatrix} = \begin{bmatrix} A & 0 & 0 & 0 \\ C_1 & -I & 0 & 0 \\ 0 & 0 & A & L_x \\ 0 & 0 & C_1 & L_y \\ \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ v(t) \\ w(t) \\ \end{bmatrix} + \begin{bmatrix} B \\ D_1 \\ 0 \\ \end{bmatrix} u(t)
\]

and the observation error satisfies

\[
e(t) = \hat{z}(t) - z(t) = C_2 x_o(t) + D_2 u(t) + L_z w(t) - C_2 x(t) - D_2 u(t) = C_2 v(t) + L_z w(t).
\]
In particular, the error is the output of the DAE system
\[
\frac{d}{dt} \begin{bmatrix} E & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v(t) \\ w(t) \end{bmatrix} = \begin{bmatrix} A & L_o \\ C_1 & L_o \end{bmatrix} \begin{bmatrix} v(t) \\ w(t) \end{bmatrix}.
\]

(10)

\[ e(t) = \begin{bmatrix} C_2 \\ L_z \end{bmatrix} \begin{bmatrix} v(t) \\ w(t) \end{bmatrix} \]

Theorem 3.3. Consider the system \( [E, A, B, C_1, C_2, D_1, D_2] \) and let \( k \in \mathbb{N}_0 \), \( L_x \in \mathbb{R}^{l \times k} \), \( L_y \in \mathbb{R}^{p_1 \times k} \) and \( L_z \in \mathbb{R}^{p_2 \times k} \). Then we have the following for the system \([E_o, A_o, B_o, C_o, D_o]\) as in (6):

(i) \([E_o, A_o, B_o, C_o, D_o]\) is an acceptor for \([E, A, B, C_1, C_2, D_1, D_2]\),

(ii) \([E_o, A_o, B_o, C_o, D_o]\) is a partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\) if, and only if,

a) \( \forall \gamma: \begin{bmatrix} E \\ 0 \end{bmatrix} \in \ker[C_2, L_z]\),

b) \( \forall \gamma: \begin{bmatrix} E \\ 0 \end{bmatrix} \in \ker[C_2, L_z]\),

(iii) \([E_o, A_o, B_o, C_o, D_o]\) is an asymptotic partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\) if, and only if, a) in (ii) holds true and

\[ \forall \lambda \in \mathcal{C}_+ : \begin{bmatrix} A & L_z \end{bmatrix} \lambda \subseteq \ker[C_2, L_z]. \]

(11)

Proof.

(i) The system \([E_o, A_o, B_o, C_o, D_o]\) is an acceptor for \([E, A, B, C_1, C_2, D_1, D_2]\), since for all \((x, u, y, z) \in \mathcal{B}_{[E, A, B, C_1, C_2, D_1, D_2]}\) we have

\[ ((\frac{\partial}{\partial t}), (w), (z)) \in \mathcal{B}_{[E_o, A_o, B_o, C_o, D_o]}. \]

(ii) \( \Rightarrow \): Suppose that \([E_o, A_o, B_o, C_o, D_o]\) is a partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\). Consider a solution \((v, w, e)\) of (10) with \(e(0) = 0\). By (7), (8) and (9) we have

\[ (0, 0, 0) \in \mathcal{B}_{[E, A, B, C_1, C_2, D_1, D_2]} \land ((\frac{\partial}{\partial t}), (w), (z), (e)) \in \mathcal{B}_{[E_o, A_o, B_o, C_o, D_o]}. \]

(12)

The definition of a partial state observer implies \(e = 0\). The statement then follows from Lemma A.2.

\( \Leftarrow: \) Assume that a) and b) are satisfied and consider \((x, u, y, z) \in \mathcal{B}_{[E, A, B, C_1, C_2, D_1, D_2]}\) and \((v, w, e, z) \in \mathcal{B}_{[E_o, A_o, B_o, C_o, D_o]}\) with \(z(0) = \hat{z}(0)\). Then \((v = x_o - x, w, e = \hat{e} - z)\) solves (10) with \(e(0) = 0\) and it follows from Lemma A.2 that \(e = 0\). This means that \([E_o, A_o, B_o, C_o, D_o]\) in (6) is a partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\).

(iii) \( \Rightarrow \): Assume that \([E_o, A_o, B_o, C_o, D_o]\) in (6) is an asymptotic partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\). Then a) in (ii) holds true. To show (11), consider a solution \((v, w, e)\) of (10). Then the relations in (12) hold true and the definition of an asymptotic partial state observer gives \(\lim_{t \to \infty} \text{ess sup}_{[t, \infty)} \|e\| = 0\). Hence, for all solutions \((v, w, e)\) of (10) we have

\[ \lim_{t \to \infty} \text{ess sup}_{[t, \infty)} \left\| \begin{bmatrix} C_2 \\ L_z \end{bmatrix} \begin{bmatrix} v(t) \\ w(t) \end{bmatrix} \right\| = 0. \]

Then Lemma A.4 implies (11).

\[ \lim_{t \to \infty} \text{ess sup}_{t} \| e(t) \| = \lim_{t \to \infty} \text{ess sup}_{t} \| [C_2, L_c] \left( \frac{w(t)}{w(t)} \right) \| = 0. \]

The system \([E_o, A_o, B_o, C_o, D_o]\) in (6) is therefore an asymptotic partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\). \(\Box\)

**Remark 3.4.** Note that in the partial state observer (6) in almost all cases we have \(E_o \neq I\), i.e., the observer is not governed by an ODE, even if the plant is an ODE \((E = I)\). However, if the system \([E, A, B, C_1, D_1] \) is impulse observable (for a definition, see e.g. the survey Berger et al. (2017)), then \(x_{E_o} - A_o\) in (6) can be constructed to have index at most one as shown in Berger and Reis (2015a). In this case there exists an equivalent observer where \(E_o = I\), see also Berger and Reis (2016).

Next we show that the partial state observer \([E_o, A_o, B_o, C_o, D_o] \in \Sigma_{l+p_1+n+k_m+p_1,p_2}\) in (6) has a universal property in a certain sense: If an (asymptotic) partial state observer exists, then it can be constructed to be of the form (6).

**Theorem 3.5.** For \([E, A, B, C_1, C_2, D_1, D_2] \in \Sigma_{l,n,m,p_1,p_2}\) the following holds true:

(i) There exists a partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\) if, and only if,

a) \(\mathcal{Y}^\lambda \left[ \begin{bmatrix} E \\ 0 \end{bmatrix} \right] \left[ \begin{bmatrix} A \\ C_1 \end{bmatrix} \right] \subseteq \ker C_2.\)

b) \(\mathcal{Y}^\lambda \left[ \begin{bmatrix} E \\ 0 \end{bmatrix} \right] \left[ \begin{bmatrix} A \\ C_1 \end{bmatrix} \right] \subseteq \ker C_2.\)

(ii) There exists an asymptotic partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\) if, and only if, a) in (i) holds true and

\[ \forall \lambda \in \mathbb{C}^+_0 : \mathcal{Y}^\lambda \left[ \begin{bmatrix} E \\ 0 \end{bmatrix} \right] \left[ \begin{bmatrix} A \\ C_1 \end{bmatrix} \right] \subseteq \ker C_2. \quad (13) \]

**Proof.** We start with proving “\(\Leftarrow\)” for (i) and (ii) together: Consider the acceptor \([E_o, A_o, B_o, C_o, D_o] \in \Sigma_{l+p_1+n+k_m+p_1,p_2}\) in (6) with \(k = 0, L_x = 0, L_y = 0, L_z = 0\) and \(L_{\xi} = 0\). Then, by Theorem 3.3 (ii) (resp. (iii)), \([E_o, A_o, B_o, C_o, D_o]\) is an (asymptotic) partial state observer, if the conditions in a) and b) (resp. a) and (13)) hold true.

It remains to prove “\(\Rightarrow\)” for (i) and (ii):

(i) Suppose that \([E_o, A_o, B_o, C_o, D_o] \in \Sigma_{l,n,m+p_1,p_2}\) is a partial state observer for \([E, A, B, C_1, C_2, D_1, D_2]\). Consider \(x \in L^1_{\text{loc}}(\mathbb{R} \to \mathbb{R}^n)\) with \(E x \in \mathcal{A}^\varepsilon(\mathbb{R} \to \mathbb{R}^l)\) and

\[ \frac{d}{dt} \left[ \begin{bmatrix} E \\ 0 \end{bmatrix} x \right] = \left[ \begin{bmatrix} A \\ C_1 \end{bmatrix} \right] x \quad \text{(14)} \]

such that \(C_2 x(0) = 0\). Then \((x, 0, 0, C_2 x) \in \mathcal{B}_{[E, A, B, C_1, C_2, D_1, D_2]}\) and

\[ (0, \left[ \begin{bmatrix} 0 \\ 0 \end{bmatrix} \right], 0) \in \mathcal{B}_{[E_o, A_o, B_o, C_o, D_o]}, \quad \text{(15)} \]

10
Remark 3.6. We consider some special cases using the notation from Theorem 3.5.

(i) Assume that $C_2 = I_{n}$. Then condition a) in Theorem 3.5 (i) is always satisfied and hence Theorem 3.5 is equivalent to (Berger & Reis, 2015a, Thm. 3.5), i.e., the partial state observer is a full state observer in this case.

(ii) Suppose that $sE - A$ is regular. By Lemma 2.1, condition b) in Theorem 3.5 (i) is equivalent to

$$\mathcal{V}_{[E,A,0,C_1]}^{*} \cap \mathcal{W}_{[E,A,0,C_1]}^{*} \subseteq \ker C_2.$$ 

It is a simple calculation that

$$\mathcal{V}_{[E,A,0,C_1]}^{*} \cap \mathcal{W}_{[E,A,0,C_1]}^{*} \subseteq \mathcal{V}_{[E,A,0,0]}^{*} \cap \mathcal{W}_{[E,A,0,0]}^{*} = \{0\},$$

where the last equality follows from regularity of $sE - A$, see (Berger et al., 2012, Prop. 2.4). Therefore, condition b) is always satisfied in this case.

(iii) A combination of (i) and (ii) shows that if $sE - A$ is regular and $C_2 = I_n$, then a (partial state) observer always exists, i.e., full state reconstruction is always possible for regular DAE systems. This was already shown in Berger and Reis (2015a).

(iv) Assume that $E = I_{n}$. Using the notation $\mathcal{O}(A,C) := [C^T,A^T C^T,\ldots,(A^{n-1})^T C^T]^T$ for some $C \in \mathbb{R}^{p \times n}$ it is a straightforward calculation that condition a) in Theorem 3.5 (i) is equivalent to

$$\mathcal{O} \left( A, \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} \right) = \mathcal{O}(A,C_1) \cap \ker C_2.$$ 

Therefore, invoking (ii), the above condition characterizes existence of a partial state observer for an ODE system.

(v) The relations derived in (i)--(iv) are depicted in Figure 3.

(vi) We like to note that it is hard to compare Theorem 3.5 to the results derived e.g. in Willems and Commault (1981), since the notion of a partial state observer is different there. Roughly speaking, in Willems and Commault (1981) a system $[I,A_0, B_0,C_0, D_0]$ is called a partial state observer for a given plant, if zero initial values of the states, i.e., $x(0) = 0$ and $x_0(0) = 0$ (using the notation in (2), (3)) implies $z(t) = \hat{z}(t)$ for all $t \geq 0$. This is different from our framework, where $z(0) = \hat{z}(0)$ implies $z(t) = \hat{z}(t)$ for all $t \geq 0$. 

By Lemma A.4 this implies (13).
4. Disturbance decoupled partial state observers

In this section we define disturbance decoupling using the intuitive approach introduced in Berger (2017). To this end, we consider a system \([E,A,0,C,0] \in \Sigma_{l,n,0,p}\) and disturbance matrix \(Q = \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p) \times q}\); the corresponding DAE is of the form (2) with \(m = 0\) and \(p_2 = 0\).

We may treat the disturbance \(d\) as the input of this system and define disturbance decoupling in terms of the set-valued input-output map of the system \([E,A,Q_1,C,Q_2] \in \Sigma_{l,n,q,p}\).

**Definition 4.1.** For a system \([E,A,B,C,D] \in \Sigma_{l,n,m,p}\) we call the set-valued map

\[
\Phi_{[E,A,B,C,D]} : \mathcal{C}^\infty(\mathbb{R} \rightarrow \mathbb{R}^m) \rightarrow \mathcal{P}(\mathcal{C}^\infty(\mathbb{R} \rightarrow \mathbb{R}^p)),
\]

\(u \mapsto \{ y \in \mathcal{C}^\infty(\mathbb{R} \rightarrow \mathbb{R}^p) \mid \exists x \in \mathcal{C}^\infty(\mathbb{R} \rightarrow \mathbb{R}^n) : (x,u,y) \in \mathcal{B}_{[E,A,B,C,D]} \}\),

the input-output map of \([E,A,B,C,D]\). Here, \(\mathcal{P}(\mathcal{M})\) denotes the power set of a set \(\mathcal{M}\).

**Definition 4.2.** Let \([E,A,0,C,0] \in \Sigma_{l,n,0,p}\) and \(Q = \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p) \times q}\). Then we call \([E,A,Q_1,C,Q_2]\) disturbance decoupled, if

\[
\forall d_1,d_2 \in \mathcal{C}^\infty(\mathbb{R} \rightarrow \mathbb{R}^q) : \Phi_{[E,A,Q_1,C,Q_2]}(d_1) = \Phi_{[E,A,Q_1,C,Q_2]}(d_2).
\]

Roughly speaking, \([E,A,Q_1,C,Q_2]\) is disturbance decoupled, if any two disturbances cannot be distinguished using knowledge of the output. The above definition generalizes the definition given in Berger (2017) to the case of output disturbances. The following characterization is a straightforward modification of (Berger, 2017, Prop. 7) to that case.

**Lemma 4.3.** Let \([E,A,0,C,0] \in \Sigma_{l,n,0,p}\) and \(Q = \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p) \times q}\). Then \([E,A,Q_1,C,Q_2]\) is disturbance decoupled if, and only if,

\[
\forall d \in \mathcal{C}^\infty(\mathbb{R} \rightarrow \mathbb{R}^q) \exists x \in \mathcal{C}^\infty(\mathbb{R} \rightarrow \mathbb{R}^n) : Cx + Q_2d = 0 \land E\dot{x} = Ax + Q_1d. \quad (16)
\]
We record a straightforward consequence of Lemma 4.3.

**Corollary 4.4.** Let \( [E,A,0,C,0] \in \Sigma_{l,n,0,p} \) and \( Q = \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p) \times q} \). Then \( [E,A,Q_1,C,Q_2] \in \Sigma_{l,n,q,p} \) is disturbance decoupled if, and only if, \( \begin{bmatrix} \begin{bmatrix} E \\ A \end{bmatrix} , \begin{bmatrix} Q_1 \\ 0 \end{bmatrix} , 0, 0 \end{bmatrix} \in \Sigma_{l+p,n,q,0} \) is disturbance decoupled.

In the following we give the definition for a disturbance decoupled partial state observer. Classically, see e.g. (Willems & Commault, 1981, p. 497), an observer has this property, if in the interconnection with the plant (cf. Figure 1) the observation error is independent of the input and the disturbance. We give the precise definition using our framework.

Consider a system \( [E,A,B,C_1,C_2,D_1,D_2] \in \Sigma_{l,n,m,p_1,p_2} \) with disturbance matrix \( Q = \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p_1+p_2) \times q} \) as in (2) and a partial state observer \( [E_o,A_o,B_o,C_o,D_o] \in \Sigma_{l_o,n_o,m+p_1,p_2} \) as in (3), where we write

\[
B_o = [B_{o,1},B_{o,2}] \in \mathbb{R}^{l_o \times (m+p_1)} \quad \text{and} \quad D_o = [D_{o,1},D_{o,2}] \in \mathbb{R}^{p_2 \times (m+p_1)}.
\]

The interconnection is depicted in Figure 1 and, after some straightforward manipulations, we may write the resulting system as

\[
\begin{aligned}
\frac{d}{dt} \begin{bmatrix} E & 0 \\ 0 & E_o \end{bmatrix} \begin{bmatrix} x \\ x_o \end{bmatrix} &= \begin{bmatrix} A & 0 \\ B_{o,2}C_1 & A_o \end{bmatrix} \begin{bmatrix} x \\ x_o \end{bmatrix} + \begin{bmatrix} B \\ B_{o,1} + B_{o,2}D_1 \\ B_{o,2}Q_2 \end{bmatrix} \begin{bmatrix} u \\ d \end{bmatrix}, \\
e &= \tilde{z} - z = \begin{bmatrix} D_{o,2}C_1 - C_2 & C_o \end{bmatrix} \begin{bmatrix} x \\ x_o \end{bmatrix} + \begin{bmatrix} D_{o,1} - D_{o,2}D_1 - D_2 \\ D_{o,2}Q_2 - Q_3 \end{bmatrix} \begin{bmatrix} u \\ d \end{bmatrix},
\end{aligned}
\]

that is

\[
[\tilde{E},\tilde{A},\tilde{B},\tilde{C},\tilde{D}] := \begin{bmatrix} E & 0 \\ 0 & E_o \end{bmatrix}, \begin{bmatrix} A & 0 \\ B_{o,2}C_1 & A_o \end{bmatrix}, \begin{bmatrix} B \\ B_{o,1} + B_{o,2}D_1 \\ B_{o,2}Q_2 \end{bmatrix}, \\
[\tilde{D}_{o,2}C_1 - C_2 & C_o], \begin{bmatrix} D_{o,1} - D_{o,2}D_1 - D_2 \\ D_{o,2}Q_2 - Q_3 \end{bmatrix} \in \Sigma_{l+\tilde{l_o}+\tilde{n_o},m+p+q,p_2}.
\]

**Definition 4.5.** We call a partial state observer \( [E_o,A_o,B_o,C_o,D_o] \in \Sigma_{l_o,n_o,m+p_1,p_2} \) disturbance decoupled for a system \( [E,A,B,C_1,C_2,D_1,D_2] \in \Sigma_{l,n,m,p_1,p_2} \) and disturbance matrix \( Q = \begin{bmatrix} Q_1 \\ Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p_1+p_2) \times q} \), if \( [\tilde{E},\tilde{A},\tilde{B},\tilde{C},\tilde{D}] \) in (19) is disturbance decoupled.

In the following we show that it is sufficient to restrict ourselves to the case of vanishing feedthrough matrices, i.e., \( D_1 = 0, D_2 = 0 \) and \( Q_2 = 0, Q_3 = 0 \). To this end, we augment the
state space of the system (2), that is we consider

\[
\begin{bmatrix}
E & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\begin{bmatrix}
x \\
v_1 \\
v_2 \\
v_3 \\
v_4 \\
\end{bmatrix}
= 
\begin{bmatrix}
A & 0 & 0 & 0 & 0 \\
0 & -I_{p_1} & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & -I_{p_2} \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\begin{bmatrix}
x \\
v_1 \\
v_2 \\
v_3 \\
v_4 \\
\end{bmatrix}
+ 
\begin{bmatrix}
B & D_1 \\
0 & 0 \\
D_2 & 0 \\
D_3 & 0 \\
\end{bmatrix}
\begin{bmatrix}
u \\
d \\
\end{bmatrix}
+ 
\begin{bmatrix}
Q_1 \\
Q_2 \\
Q_3 \\
\end{bmatrix}
d,
\]

Lemma 4.6. A partial state observer \([E_o,A_o,B_o,C_o,D_o] \in \Sigma_{l_o,n_o,m+p_1,p_2}\) is disturbance decoupled for a system \([E,A,B,C_1,C_2,D_1,D_2] \in \Sigma_{l,n,m,p_1,p_2}\) and disturbance matrix \(Q \in \mathbb{R}^{(l+p_1+p_2) \times q}\) if, and only if, using the notation from (20), \([E_o,A_o,B_o,C_o,D_o] \in \Sigma_{l+2p_1+2p_2,n+2p_1+2p_2,m,p_1,p_2}\) and disturbance matrix \([Q_o]\).

Proof. The statement follows from a straightforward calculation.

5. Disturbance decoupled estimation

In this section we consider the disturbance decoupled estimation problem. In view of Lemma 4.6 we first consider the case of zero feedthrough matrices \((D_1 = 0\) and \(D_2 = 0\)) and undisturbed output equations \((Q_2 = 0\) and \(Q_3 = 0\)). That is, for a given system \([E,A,B,C_1,C_2,0,0] \in \Sigma_{l,n,m,p_1,p_2}\) and disturbance matrix \(Q \in \mathbb{R}^{l \times q}\) we seek a partial state observer \([E_o,A_o,B_o,C_o,D_o] \in \Sigma_{l_o,n_o,m+p_1,p_2}\) which is disturbance decoupled for \([E,A,B,C_1,C_2,0,0]\) and \([Q_o]\) or, equivalently, invoking Definition 4.5 and Corollary 4.4,

\[
\begin{bmatrix}
E & 0 \\
0 & E_o \\
B_{o,2}C_1 & A_o \\
D_{o,2}C_1 - C_2 & D_o \\
\end{bmatrix}
= 
\begin{bmatrix}
A & 0 \\
0 & 0 \\
B & Q \\
0 & 0 \\
\end{bmatrix}
\begin{bmatrix}
B_{o,1} & 0 \\
0 & 0 \\
D_{o,1} & 0 \\
0 & 0 \\
\end{bmatrix}
\]
is disturbance decoupled, \((21)\)

where we use the partitioning \((17)\).

Theorem 5.1. Let \([E,A,B,C_1,C_2,0,0] \in \Sigma_{l,n,m,p_1,p_2}\) and \(Q \in \mathbb{R}^{l \times q}\). There exists a partial state observer \([E_o,A_o,B_o,C_o,D_o] \in \Sigma_{l_o,n_o,m+p_1,p_2}\) such that \((21)\) is satisfied if, and only if, the following statements hold:
Let a partial state observer \([E_o, A_o, B_o, C_o, D_o] \in \Sigma_{L_o,n_o,m+p_1,p_2}\) of the form (6) with \(k \in \mathbb{N}_0\), \(L_x \in \mathbb{R}^{l \times k}\), \(L_y \in \mathbb{R}^{p_1 \times k}\), and \(L_z \in \mathbb{R}^{p_2 \times k}\). If we assume this form, then Lemma 4.3 yields that (21) is equivalent to

\[
\forall (u, d) \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^m \times \mathbb{R}^q) \ni (x_1, x_2, x_3) \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^n \times \mathbb{R}^n) : \quad
E \dot{x} = Ax + Bu + Qd,
\]

where \(x = \begin{bmatrix} x_1 & x_2 & x_3 \end{bmatrix}^T\) and \(A, B, C, D, Q, L \in \mathbb{R}^{n \times n}, \mathbb{R}^{n \times m}, \mathbb{R}^{n \times q}, \mathbb{R}^{n \times r}, \mathbb{R}^{n \times q}, \mathbb{R}^{n \times r}\), respectively. Let \(v = x_2 - x_1\) we obtain the equivalent decoupled conditions

\[
\forall (u, d) \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^m \times \mathbb{R}^q) \ni v \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^n) : \quad E \dot{v} = Av + L_v - Qd,
\]

which is always satisfied by statement (i), and

\[
\forall d \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^q) \ni (v, x_3) \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^q) : \quad
E \dot{v} = Av + L_v - Qd,
\]

\[
0 = C_1 v + L_v x_3,
\]

\[
0 = C_2 v + L_v x_3.
\]

It remains to find \(L_x, L_y, L_z\) such that (22) is satisfied and \([E_o, A_o, B_o, C_o, D_o]\) is a partial state observer, i.e., conditions a) and b) in Theorem 3.3 (ii) are satisfied. We choose \(k = q, L_x = Q, L_y = 0\) and \(L_z = 0\). Then (22) is obviously satisfied, since for any \(d \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^q)\) we may choose \(v = 0\) and \(x_3 = d\). Condition a) in Theorem 3.3 (ii) is equivalent to (ii) and condition b) in Theorem 3.3 (ii) is equivalent to

\[
\mathcal{Y}'^e \cap \mathcal{W}'^e \subseteq \ker[C_2, 0],
\]

which, invoking Lemma 2.1, follows from statement (iii).

\(\Rightarrow\): Let a partial state observer \([E_o, A_o, B_o, C_o, D_o] \in \Sigma_{L_o,n_o,m+p_1,p_2}\) such that (21) is satisfied be given. From Lemma 4.3 it is clear that (i) must be satisfied. For (ii) and (iii) we show that

\[
\forall (x, u, d, y, z, x_0, \hat{z}) \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^q \times \mathbb{R}^{p_1} \times \mathbb{R}^{p_2} \times \mathbb{R}^{n_o} \times \mathbb{R}^{p_2}) : \quad
(\chi, (u', y), z, x_0, \hat{z}) \in \mathcal{B}[E_o, A_o, B_o, C_o, D_o] \cap \mathcal{W}[E_o, A_o, B_o, C_o, D_o] \quad \Rightarrow \quad \hat{z} = z.
\]

Let \((x, u', y, z) \in \mathcal{B}[E_o, A_o, B_o, C_o, D_o] \) and \((x_0, \hat{z}) \in \mathcal{B}[E_o, A_o, B_o, C_o, D_o] \) be smooth trajectories such that \(z(0) = \hat{z}(0)\). Furthermore, by (21) and Lemma 4.3 there exist \(\hat{x} \in \mathcal{C}^\infty(\mathbb{R} \to \mathbb{R}^n)\),
\( \tilde{x}_o \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^{n_o}) \) such that

\[
\frac{d}{dt} \begin{bmatrix}
E & 0 \\
0 & E_o \\
0 & 0
\end{bmatrix} \begin{bmatrix}
\tilde{x} \\
\tilde{x}_o
\end{bmatrix} = \begin{bmatrix}
A & 0 \\
B_{o,2}C_1 & A_o \\
D_{o,2}C_1 - C_2 & C_o
\end{bmatrix} \begin{bmatrix}
\tilde{x} \\
\tilde{x}_o
\end{bmatrix} + \begin{bmatrix}
B & Q \\
B_{o,1} & 0
\end{bmatrix} \begin{bmatrix}
u \\
d
\end{bmatrix}.
\]

The new variables \( v := \tilde{x} - x \) and \( w := \tilde{x}_o - x_o \) satisfy

\[
E \dot{v} = Av, \\
E_o \dot{w} = A_o w + B_{o,2} C_1 v,
\]

and

\[
\dot{z} - z = C_o x_o + D_{o,1} u + D_{o,2} C_1 x - C_2 x - (D_{o,2} C_1 - C_2) \tilde{x} - C_0 \tilde{x}_o - D_{o,1} u = (C_2 - D_{o,2} C_1) \nu - C_o w,
\]

thus

\[
C_o w + D_{o,2} C_1 v = C_2 v - (\dot{z} - z).
\]

Therefore,

\[
(v, 0, C_1 v, C_2 v) \in \mathcal{B}_{[E, A, B, C_1, C_2, 0, 0]} \quad \land \quad (w, (0, C_1 \nu), C_2 v - (\dot{z} - z)) \in \mathcal{B}_{[E_o, A_o, B_o, C_o, D_o]},
\]

and since \([E_o, A_o, B_o, C_o, D_o]\) is a partial state observer and \(C_2 \nu(0) = C_2 \nu(0) - (\dot{z}(0) - z(0))\) we obtain

\[
C_2 \nu = C_2 v - (\dot{z} - z),
\]

hence \( \dot{z} = z \), which proves (24). It remains to consider \( x \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^n) \) and \( d \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^q) \) such that \((x, (0, 0), 0, 0) \in \mathcal{B}_{[E, A, B, Q, C_1, C_2, 0, 0]}\) with \(C_2 x(0) = 0\). Since \((0, (0, 0), 0) \in \mathcal{B}_{[E_o, A_o, B_o, C_o, D_o]}\) it follows from (24) that \(C_2 x = 0\), i.e., we have shown that

\[
\forall x \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^n), \quad d \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^q) : \\
(E \dot{x} = Ax + Qd \quad \land \quad C_1 x = 0 \quad \land \quad C_2 x(0) = 0) \quad \implies \quad C_2 x = 0.
\]

By Lemma A.2 this implies (ii) and (23). Invoking Lemma 2.1, (23) is equivalent to (iii). \( \square \)

**Remark 5.2.**

(i) It may seem strange that condition (i) in Theorem 5.1 involves a condition on \( B \), while in the ODE case the solution of the disturbance decoupled estimation problem does not involve such a condition, see Willems and Commault (1981). Condition (i) is specific to the DAE case and always satisfied in the ODE case, since it characterizes the existence of a solution \( x \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^n) \) of

\[
E \dot{x} = Ax + Bu + Qd
\]

for any given input \( u \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^m) \) and any disturbance \( d \in \mathscr{C}^\infty(\mathbb{R} \to \mathbb{R}^q) \). If \( sE - A \) is not regular, then this condition may not be met.
(ii) The intuition for conditions (ii) and (iii) in Theorem 5.1 is as follows: Since only inputs and outputs are known to the partial state observer, the dynamics of the system

\[
\frac{d}{dt}Ex = Ax + Qd,
\]

\[
0 = C_1x
\]

are hidden from the observer. More precisely, for any \((x, \begin{pmatrix} u_0 \\ y \\ z \end{pmatrix}, y, z) \in \mathbb{R}^{[E,A,B,Q,C_1,b,0,0]}\) and a solution \((\tilde{x}, d)\) of (25) we have

\[(x + \tilde{x}, \begin{pmatrix} u_0 \\ y \\ z + C_2\tilde{x} \end{pmatrix}) \in \mathbb{R}^{[E,A,B,Q,C_1,b,0,0]}\]

i.e., another solution with the same input \(u\) and the same output \(y\); the disturbance \(d\) is not visible for the observer. Now, conditions (ii) and (iii) guarantee that the partial state observer is still able to reconstruct the controlled output from its initial condition, i.e., that if \(C_2\tilde{x}(0) = 0\), then we have \(C_2\tilde{x} = 0\), see also Lemma A.2.

Utilizing a more geometric interpretation, condition (ii) states that the unobservable space of the ODE part of the DAE (25), where \((\tilde{d})\) is treated as the state, with respect to the controlled output \(z = C_2x\) is equal to the kernel of the output matrix \(C_2\), i.e., if the initial state is not visible at the output, then it is not visible at the output for all other time instants. The unobservable space is given by \(\mathcal{Y}_{E,A,Q,C_1}^\dagger \cap \mathcal{Y}_{E,A,Q,C_1}^\dagger\), see Berger et al. (2017). Condition (iii) guarantees that the completely controllable part of \(\frac{d}{dt}Ex = Ax + Qd\) (where \(d\) is viewed as an input) restricted to \(k C_1\), i.e., of the system

\[ETx = ATx + Qd, \quad \text{im} T = \ker C_1,\]

lies in \(\ker C_2\), so that it is not visible in the controlled output \(z = C_2x\). Geometrically, the completely controllable part is characterized by the reachable space of the system, which in turn is given by the intersection of the generalized Wong sequences \(\mathcal{Y}_{E,A,Q,C_1}^\dagger \cap \mathcal{Y}_{E,A,Q,C_1}^\dagger\), see Berger and Reis (2013); Berger and Trenn (2014).

(iii) In Willems and Commault (1981) the following result has been derived: For \([I,A,B,C_1,C_2,b,0,0] \in \Sigma_{n,m,m_1,p_1}^n\) and \(Q \in \mathbb{R}^{l \times q}\) there exists \([I,A_0,B_0,C_0,D_0] \in \Sigma_{n_0,n_0,m+1,p_2}^n\) such that the interconnection (18) has zero transfer function, i.e.,

\[
[D_{o,2}C_1 - C_2 \quad C_0] \left[ \begin{array}{cc} sl - A & 0 \\ -B_{o,2}C_1 & sl - A_0 \end{array} \right]^{-1} \left[ \begin{array}{cc} B \\ B_{o,1} \end{array} \right] + \left[ \begin{array}{cc} D_{o,1} \\ 0 \end{array} \right] = 0
\]

if, and only if,

\[\mathcal{Y}_{[I,A,Q,C_1]}^\dagger \subseteq \ker C_2.\]

This may be compared to Theorem 5.1 as follows: Condition (i) is always satisfied since \(E = I\); condition (ii) is due to the different definition of the partial state observer compared to Willems and Commault (1981), see Remark 3.6 (v), hence such a condition does not appear there; condition (iii) is weaker than (26), where \(\mathcal{Y}_{[I,A,Q,C_1]}^\dagger\) is considered instead of \(\mathcal{Y}_{[I,A,Q,C_1]}^\dagger \cap \mathcal{Y}_{[I,A,Q,C_1]}^\dagger\). The reason for this weaker condition is that we allow for a DAE observer (i.e., \(E_o\) in (3) is not invertible in general) even if the plant is governed by an ODE.
The existence of a disturbance decoupled partial state observer for a general system 
\([E, A, B, C_1, C_2, D_1, D_2] \in \Sigma_{i,n,m,p_1,p_2}\) and disturbance matrix \(Q = \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p_1+p_2) \times q}\), i.e., with nonzero feedthrough matrices, follows from Theorem 5.1 and Lemma 4.6. In the case of an undisturbed controlled output, that is \(Q_3 = 0\), the conditions simplify a lot; this is the result of the following theorem.

**Theorem 5.3.** There exists a disturbance decoupled partial state observer 
\([E_0, A_0, B_0, C_0, D_0] \in \Sigma_{i,n,m,p_1,p_2}\) for a system 
\([E, A, B, C_1, C_2, D_1, D_2] \in \Sigma_{i,n,m,p_1,p_2}\) and disturbance matrix \(Q = \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \in \mathbb{R}^{(l+p_1+p_2) \times q}\) if, and only if, the following statements hold:

1. \(\text{im} [B, Q_1] \subseteq \mathcal{E} \gamma^{*}_{[E, A, 0, 0]} + A \mathcal{W}^{*}_{[E, A, 0, 0]}\),
2. \(\gamma^{*}_{[\hat{E} \hat{A}, 0, 0]} = \gamma^{*}_{[E, A, 0, 0]} \cap \ker[C_2, 0]\),
3. \(\gamma^{*}_{[\hat{E} \hat{A}, 0, 0]} \subseteq \ker[C_2, 0]\).

**Proof.** Using the notation in (20), Lemma 4.6 and Theorem 5.1 give that there exists a disturbance decoupled partial state observer for 
\([E, A, B, C_1, C_2, D_1, D_2]\) and disturbance matrix \(Q = \begin{bmatrix} Q_1 & Q_2 \end{bmatrix}\), if, and only if,

(a) \(\text{im} [\hat{B}, \hat{Q}] \subseteq \mathcal{E} \gamma^{*}_{[E, A, 0, 0]} + \hat{A} \mathcal{W}^{*}_{[E, A, 0, 0]}\),
(b) \(\gamma^{*}_{[\hat{E} \hat{A}, 0, 0]} = \gamma^{*}_{[E, A, 0, 0]} \cap \ker[C_2, 0]\),
(c) \(\gamma^{*}_{[\hat{E} \hat{A}, 0, 0]} \subseteq \ker[C_2, 0]\).

We proof that (a)–(b) are equivalent to (i)–(iii) by proceeding in several steps.

**Step 1:** We show that (a) is equivalent to (i). A simple inductive argument gives that

\[
\gamma^{*}_{[E, A, 0, 0]} = \gamma^{*}_{[E, A, 0, 0]} \times \{0\} \times \{0\} \times \{0\},
\]

\[
\mathcal{W}^{*}_{[E, A, 0, 0]} = \mathcal{W}^{*}_{[E, A, 0, 0]} \times \mathbb{R}^{p_1} \times \mathbb{R}^{p_1} \times \mathbb{R}^{p_2} \times \mathbb{R}^{p_2},
\]

hence

\[
\mathcal{E} \gamma^{*}_{[E, A, 0, 0]} + \hat{A} \mathcal{W}^{*}_{[E, A, 0, 0]} = (E \gamma^{*}_{[E, A, 0, 0]} + A \mathcal{W}^{*}_{[E, A, 0, 0]}) \times \mathbb{R}^{p_1} \times \mathbb{R}^{p_1} \times \mathbb{R}^{p_2} \times \mathbb{R}^{p_2}.
\]

The statement then follows from observing that

\[
\text{im} [\hat{B}, \hat{Q}] = \text{im} \begin{bmatrix} B & Q_1 & D_1 & 0 & Q_2 & D_2 & 0 & 0 & Q_3 & 0 \end{bmatrix}.
\]

**Step 2:** We show that (b) is equivalent to (ii). We first prove by induction that

\[
\forall i \in \mathbb{N}: \gamma^{i}_{[E, A, 0, 0]} \cap \ker[C_2, 0] = \left[\begin{array}{cccccc} l_0 & 0 & 0 & 0 & 0 & 0 \\ 0 & l_0 & 0 & 0 & 0 & 0 \\ 0 & 0 & l_0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -C_0 & 0 & 0 \\ 0 & 0 & 0 & 0 & l_0 & 0 \\ 0 & 0 & 0 & 0 & 0 & l_0 \end{array}\right] \gamma^{i}_{[E, A, 0, 0]} \cap \ker[C_2, 0].
\]
For $i = 1$ the statement follows from
\[
\mathcal{Y}^1_i = \begin{bmatrix} \hat{E} & \hat{A} & \hat{Q} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \hat{C}_1 & 0 \end{bmatrix} \mathcal{Y}_{(0,0)}^{i,0},\mathcal{Y}_{(C_2,0)}^{i,0},
\]
\[
= \left\{ \begin{array}{l}
x_1 \\ \vdots \\ x_6 \end{array} \right\} \in \mathbb{R}^{n+2p_1+2p_2+q} 
\]
We show by induction that

$$\forall i \in \mathbb{N} : \mathcal{W}_i = \left[ \begin{array}{c} 1 \\ -c_i \\ 0 \\ 0 \end{array} \right].$$

For $i = 1$ this follows from

$$\mathcal{W}_1 = \left\{ \begin{array}{ll} (x_1) \in \mathbb{R}^{n+2p_1+2p_2} & \exists y \in \mathbb{R}_n, z \in \mathbb{R}^q : Ax_1 = Ey + Q_1z, \\ \vdots & x_2 = 0, -x_3 = Q_2z, x_4 = 0, \\ (x_5) & x_5 = 0, C_1x_1 + x_2 + x_3 = 0 \end{array} \right\}$$

= \left\{ \begin{array}{ll} (x_1) \in \mathbb{R}^{n+2p_1+2p_2} & x_1 \in \mathcal{W}_1, x_2 = 0, x_3 = -C_1x_1, \\ \vdots & x_4 = 0, x_5 = 0 \end{array} \right\}.

Now assume that the statement is true for some $i \in \mathbb{N}$, then

$$\mathcal{W}_{i+1} = \left\{ \begin{array}{ll} (x_1) \in \mathbb{R}^{n+2p_1+2p_2} & \exists y \in \mathcal{W}_i, z \in \mathbb{R}^q : Ax_1 = Ey + Q_1z, \\ \vdots & x_2 = 0, -x_3 = Q_2z, x_4 = 0, \\ (x_5) & x_5 = 0, C_1x_1 + x_2 + x_3 = 0 \end{array} \right\}$$

= \left\{ \begin{array}{ll} (x_1) \in \mathbb{R}^{n+2p_1+2p_2} & x_1 \in \mathcal{W}_{i+1}, x_2 = 0, x_3 = -C_1x_1, \\ \vdots & x_4 = 0, x_5 = 0 \end{array} \right\}.

Next, we show by induction that

$$\forall i \in \mathbb{N} : \mathcal{W}_i = (\mathcal{W}_i \times \mathbb{R}^{2p_1+2p_2}) \cap \ker \hat{C}_1.$$

For $i = 1$ we have

$$\mathcal{W}_1 = \left\{ \begin{array}{ll} (x_1) \in \mathbb{R}^{n+2p_1+2p_2} & \exists z \in \mathbb{R}^q : Ex_1 = Q_1z, \\ \vdots & 0 = Q_2z, C_1x_1 + x_2 + x_3 = 0 \end{array} \right\}$$

= $(\mathcal{W}_1 \times \mathbb{R}^{2p_1+2p_2}) \cap \ker \hat{C}_1$.

Assume that the statement is true for some $i \in \mathbb{N}$, then we have

$$\mathcal{W}_{i+1} = \left\{ \begin{array}{ll} (x_1) \in \mathbb{R}^{n+2p_1+2p_2} & \exists (y_1) \in \mathcal{W}_i, z \in \mathbb{R}^q : Ey_1 = Q_1z, y_2 = 0, \\ \vdots & y_3 = Q_2z, y_4 = 0, y_5 = 0, \\ (x_5) & C_1x_1 + x_2 + x_3 = 0 \end{array} \right\}$$

Assume that the statement is true for some $i \in \mathbb{N}$, then we have

$$\mathcal{W}_{i+1} = \left\{ \begin{array}{ll} (x_1) \in \mathbb{R}^{n+2p_1+2p_2} & \exists (y_1) \in \mathcal{W}_i, z \in \mathbb{R}^q : Ey_1 = Q_1z, y_2 = 0, \\ \vdots & y_3 = Q_2z, y_4 = 0, y_5 = 0, \\ (x_5) & C_1x_1 + x_2 + x_3 = 0 \end{array} \right\}.$$
and since $\mathcal{W}_t \subseteq \ker \hat{C}_t$ it follows $0 = C_1 y_1 + y_2 + y_3 = C_1 y_1 + Q_2 z$ and hence

$$\mathcal{W}_{i+1} = \left\{ \begin{pmatrix} x_1 \\ \vdots \\ x_5 \end{pmatrix} \in \mathbb{R}^{n+2p_1+2p_2} \mid \exists y_1 \in \mathcal{W}_i, z \in \mathbb{R}^q : \begin{array}{l} E x_1 = A y_1 + Q z, \\ 0 = C_1 y_1 + Q_2 z, \\ C_1 x_1 + x_2 + x_3 = 0 \end{array} \right\}$$

\[(\mathcal{W}_{i+1} \times \mathbb{R}^{2p_1+2p_2}) \cap \ker \hat{C}_i.\]

Invoking that $\forall [E, A, \hat{Q}, \hat{C}_1] \subseteq \ker \hat{C}_1$ we may infer that

\[(c) \iff \begin{bmatrix} L_0 \\ -C_1 \\ 0 \\ 0 \end{bmatrix}^{(\hat{Q}, [E, A], \hat{Q}, \hat{C}_1)} \cap \left( \hat{W}_+ \left[ \begin{bmatrix} E \\ 0 \\ 0 \\ 0 \\ [A] \end{bmatrix}, [\hat{Q}, \hat{C}_1], [0], 0 \right] \times \mathbb{R}^{2p_1+2p_2} \right) \subseteq \ker \left[ C_2, 0, 0, I_{p_1}, I_{p_2} \right].\]

\[(\hat{W}_+ \cap \mathbb{R}^{n+q}) \cap \left[ \begin{bmatrix} E \\ 0 \\ 0 \\ 0 \\ [A] \end{bmatrix}, [\hat{Q}, \hat{C}_1], [0], 0 \right] \subseteq \ker C_2 \iff (iii).\]

In the remainder of this section we consider the special case of full state estimation (i.e., $C_2 = I$) and show that the conditions (i)-(iii) in Theorem 5.1 simplify in this case.

**Corollary 5.4.** Let $[E, A, B, C_1, I_n, 0, 0] \in \Sigma_{n, m, p_1, p_2}$ and $Q \in \mathbb{R}^{l \times q}$ with $\text{rk } Q = q$. There exists a partial state observer $[E_o, A_o, B_o, C_o, D_o] \in \Sigma_{n_o, n_o + m + p_1, p_2}$ such that (21) is satisfied if, and only if, the following statements hold:

(a) $\text{im}[B, Q] \subseteq \mathcal{Y}^*_{[E, A, 0, 0]} + A \mathcal{W}^*_{[E, A, 0, 0]}$,

(b) $\text{rk}_{\mathbb{R}[s]} \begin{bmatrix} s E - A \\ C_1 \end{bmatrix} = n + q$.

**Proof.** By Theorem 5.1 it suffices to prove that conditions (ii) and (iii) in Theorem 5.1 are equivalent to condition (b).

$\Rightarrow$: Assume that conditions (ii) and (iii) in Theorem 5.1 are true. By Lemma 2.1, (iii) is equivalent to

$$\forall [E, A, \hat{Q}, \hat{C}_1] \subseteq \ker [I_n, 0].$$

Now let

$$\begin{pmatrix} 0 \\ x_2 \end{pmatrix} \in \mathcal{Y}^*_{[E, 0, \hat{Q}, \hat{C}_1], [0, 0, 0]} \cap \mathcal{W}^*_{[E, 0, \hat{Q}, \hat{C}_1], [0, 0, 0]},$$

then

$$\begin{pmatrix} Q_{x_2} \\ 0 \end{pmatrix} = \begin{bmatrix} A \\ C_1 \\ 0 \end{bmatrix} \begin{pmatrix} 0 \\ x_2 \end{pmatrix} \in \begin{bmatrix} A \\ C_1 \\ 0 \end{bmatrix} \left( \mathcal{Y}^*_{[E, 0, \hat{Q}, \hat{C}_1], [0, 0, 0]} \cap \mathcal{W}^*_{[E, 0, \hat{Q}, \hat{C}_1], [0, 0, 0]} \right),$$

$$= \begin{bmatrix} E \\ 0 \\ 0 \end{bmatrix} \left( \mathcal{Y}^*_{[E, 0, \hat{Q}, \hat{C}_1], [0, 0, 0]} \cap \mathcal{W}^*_{[E, 0, \hat{Q}, \hat{C}_1], [0, 0, 0]} \right).$$

where the last equality follows from (Berger & Trenn, 2012, Lem. 4.4). Then (27) implies
Furthermore, since $rk Q = q$, thus we have shown
\[
\mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} \cap \mathcal{W}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} = \{0\}. \tag{28}
\]
By a combination of (Berger & Reis, 2013, Cor. 5.1 & 5.2) and (Berger & Trenn, 2012, Thm. 2.6) it follows that condition (28) is equivalent to (b).

$\Leftarrow$: As shown above it follows from (b) that (28) is true and this implies (iii) in Theorem 5.1. Since
\[
\ker \left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right] \subseteq \mathcal{W}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0}
\]
it follows that
\[
\ker[I_n, 0] \cap \mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} \subseteq \ker \left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right] \cap \mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} \subseteq \mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} \cap \mathcal{W}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} = \{0\}.
\]
Furthermore, since $rk Q = q$ and $C_2 = I_n$ we have that
\[
\mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} \subseteq \mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} = \ker \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right] \cap \ker[I_n, 0] = \{0\},
\]
and hence we may conclude that (ii) in Theorem 5.1 is true. \hfill \Box

Note that, if $sE - A$ is regular, then, using the notation from Corollary 5.4, condition (i) in Corollary 5.4 is always satisfied by Remark 5.2, hence in this case the DDEP with $C_2 = I_n$ and $rk Q = q$ is solvable if, and only if, condition (ii) in Corollary 5.4 is true.

6. Disturbance decoupled asymptotic estimation

In this section we consider the problem of disturbance decoupled asymptotic estimation and derive a characterization for the case of zero feedthrough matrices. Similar to Section 5, the general case follows from Lemma 4.6. We omit the analog of Theorem 5.3 here.

**Theorem 6.1.** Let $[E, A, B, C_1, C_2, 0, 0] \in \Sigma_{l,n,m,p_1,p_2}$ and $Q \in \mathbb{R}^{l \times d}$, there exists an asymptotic partial state observer $[E_o, A_o, B_o, C_o, D_o] \in \Sigma_{l_o,n_o,m+p_1,p_2}$ such that (21) is satisfied if, and only if, the following statements hold:

(i) $\text{im}[B, Q] \subseteq E \mathcal{V}^s_{[E, A, 0, 0]} + A \mathcal{W}^s_{[E, A, 0, 0]}$

(ii) $\mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} = \mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right], 0, 0} \cap \ker[C_2, 0],$

(iii) $\forall \lambda \in \mathbb{C}^+ : \mathcal{V}^s_{\left[ \begin{array}{c|c} E & 0 \\ \hline 0 & 0 \end{array} \right], \left[ \begin{array}{c|c} A & \mathcal{O} \\ \hline C_1 & \mathcal{O} \end{array} \right]} \subseteq \ker[C_2, 0].$

**Proof.** $\Leftarrow$: As in the proof of Theorem 5.1 we choose $[E_o, A_o, B_o, C_o, D_o]$ to be of the form (6) with $k = q$, $L_k = Q$, $L_q = 0$ and $L_2 = 0$. Since (iii) together with (4) and Lemma 2.1 implies condition (iii) in Theorem 5.1, it follows from the latter that $[E_o, A_o, B_o, C_o, D_o]$ is a disturbance decoupled partial state observer for $[E, A, B, C_1, C_2, 0, 0]$. To show that
$[E_0, A_0, B_0, C_0, D_0]$ is asymptotic we apply Theorem 3.3 and need to show that (11) is true for $L_x = Q$, $L_y = 0$ and $L_z = 0$, but this is immediate from (iii).

$\Rightarrow$: Let an asymptotic partial state observer $[E_0, A_0, B_0, C_0, D_0] \in \Sigma_{l, n, m, P_1, P_2}$ such that (21) is satisfied be given. Then Theorem 6.1 implies that (i) and (ii) are satisfied. For (iii) we show that

$$\forall (x, u, d, y, z, x_0, \hat{x}) \in C^\infty(\mathbb{R} \to \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^q \times \mathbb{R}^{P_1} \times \mathbb{R}^{P_2} \times \mathbb{R}^{P_3} \times \mathbb{R}^{P_4}) :$$

$$\left( (x, (y^T), y, z) \in \mathcal{B}[E, A, [B, Q, C_1, C_2, 0, 0] \land (x_0, (\hat{y}^T), \hat{z}) \in \mathcal{B}[E_0, A_0, B_0, C_0, D_0] \right)$$

$$\lim_{t \to \infty} \left( \frac{\dot{x}(t) - z(t)}{t} \right) = 0.$$

Let $(x, (y^T), y, z) \in \mathcal{B}[E, A, [B, Q, C_1, C_2, 0, 0]$ and $(x_0, (\hat{y}^T), \hat{z}) \in \mathcal{B}[E_0, A_0, B_0, C_0, D_0]$ be smooth trajectories. By (21) there exist $\hat{x} \in C^\infty(\mathbb{R} \to \mathbb{R}^n), \tilde{x}_0 \in C^\infty(\mathbb{R} \to \mathbb{R}^n)$ such that

$$\frac{d}{dt} \begin{bmatrix} E & 0 \\ 0 & E_0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \hat{x} \\ \tilde{x}_0 \end{bmatrix} = \begin{bmatrix} A & 0 \\ B_{o, 2} C_1 & A_o \\ D_{o, 2} C_1 - C_2 & C_o \end{bmatrix} \begin{bmatrix} \hat{x} \\ \tilde{x}_0 \end{bmatrix} + \begin{bmatrix} B & Q \\ B_{o, 1} & 0 \\ D_{o, 1} & 0 \end{bmatrix} \begin{bmatrix} u \\ d \end{bmatrix}.$$  

As in the proof of Theorem 5.1 we may show that the new variables $v := \hat{x} - x$ and $w := \tilde{x}_0 - x_0$ satisfy

$$(v, 0, C_1 v, C_2 v) \in \mathcal{B}[E, A, B, C_1, C_2, 0, 0] \land (w, (0_{C_1 v}^T), C_2 v - (\hat{z} - \tilde{x})) \in \mathcal{B}[E_0, A_0, B_0, C_0, D_0].$$

Since $[E_0, A_0, B_0, C_0, D_0]$ is an asymptotic partial state observer we obtain

$$0 = \lim_{t \to \infty} \left( (C_2 v(t) - (\hat{z}(t) - \tilde{x}(t))) - C_2 v(t) \right) = \lim_{t \to \infty} \left( \frac{\dot{z}(t) - z(t)}{t} \right),$$

which proves (29). It remains to consider $x \in C^\infty(\mathbb{R} \to \mathbb{R}^n)$ and $d \in C^\infty(\mathbb{R} \to \mathbb{R}^q)$ such that

$$(x, (y^T), 0, C_2 x) \in \mathcal{B}[E, A, [B, Q, C_1, C_2, 0, 0].$$

Since $(0, (0^T), 0) \in \mathcal{B}[E_0, A_0, B_0, C_0, D_0]$ it follows from (29) that

$$\lim_{t \to \infty} C_2 x(t) = 0, \text{ i.e., we have shown that}$$

$$\forall x \in C^\infty(\mathbb{R} \to \mathbb{R}^n), \ d \in C^\infty(\mathbb{R} \to \mathbb{R}^q) : \ (E \dot{x} = Ax + Qd \land C_1 x = 0) \implies \lim_{t \to \infty} C_2 x(t) = 0.$$

By Lemma A.4 this implies (iii). $\square$

The characterization of existence of disturbance decoupled asymptotic partial state observers for ODE systems ($E = I$) can be compared to the result in Willems and Commault (1981) similar as in Remark 5.2.

Concluding this section we consider the special case of full state asymptotic estimation (i.e., $C_2 = I$) and show that the conditions (i)–(iii) in Theorem 6.1 simplify in this case.

**Corollary 6.2.** Let $[E, A, B, C_1, I, 0, 0] \in \Sigma_{l, n, m, P_1, P_2}$ and $Q \in \mathbb{R}^{l \times q}$ with $\text{rk} Q = q$. There exists an asymptotic partial state observer $[E_0, A_0, B_0, C_0, D_0] \in \Sigma_{l, n, m, P_1, P_2}$ such that (21) is satisfied if, and only if, the following statements hold:

1. $\text{im}[B, Q] \subseteq E \mathcal{V}_{[E, A, 0, 0]} + A \mathcal{W}_{[E, A, 0, 0]},$

2. $\forall \lambda \in \mathbb{C} : \text{rk}_C \left[ \begin{bmatrix} \lambda E - A \\ C_1 \\ 0 \end{bmatrix} \right] = n + q.$

**Proof.** By Theorem 6.1 it suffices to prove that conditions (ii) and (iii) in Theorem 6.1 are equivalent to condition (b).
\[ (x_1, x_2) \in \mathcal{W}^* \left( \begin{bmatrix} E & 0 & 0 \\ 0 & C_1 & 0 \end{bmatrix} \right) \lambda. \]

By (iii) we find that \( x_1 = 0 \) and furthermore
\[
\mathcal{W}^* \left( \begin{bmatrix} E & 0 & 0 \\ 0 & C_1 & 0 \end{bmatrix} \right) \lambda = \ker \begin{bmatrix} A - \lambda E \\ C_1 \\ 0 \end{bmatrix}.
\]

This implies \( Qx_2 = 0 \) and hence \( x_2 = 0 \), thus we obtain
\[
\mathcal{W}^* \left( \begin{bmatrix} E & 0 & 0 \\ 0 & C_1 & 0 \end{bmatrix} \right) \lambda = \{0\}.
\]

Since
\[
\ker \begin{bmatrix} A - \lambda E \\ C_1 \\ 0 \end{bmatrix} = \mathcal{W}^* \left( \begin{bmatrix} E & 0 & 0 \\ 0 & C_1 & 0 \end{bmatrix} \right) \lambda \subseteq \mathcal{W}^* \left( \begin{bmatrix} E & 0 & 0 \\ 0 & C_1 & 0 \end{bmatrix} \right) \lambda = \{0\}
\]
we may infer (b).

\( \Leftarrow \): Condition (b) in particular implies condition (b) in Corollary 5.4 and hence it follows that condition (ii) in Theorem 6.1 is true. Condition (iii) in Theorem 6.1 follows from the fact that by (b) we have, for all \( \lambda \in \mathbb{C}_+ \),
\[
\ker \begin{bmatrix} A - \lambda E \\ C_1 \\ 0 \end{bmatrix} = \{0\},
\]
which implies
\[
\mathcal{W}^* \left( \begin{bmatrix} E & 0 & 0 \\ 0 & C_1 & 0 \end{bmatrix} \right) \lambda = \mathcal{W}^* \left( \begin{bmatrix} E & 0 & 0 \\ 0 & C_1 & 0 \end{bmatrix} \right) \lambda = \{0\}. \]

For the case of regular \( sE - A \), Corollary 6.2 was already proved in (Dai, 1989, Thm. 4-4.3).

7. Conclusion

In the present paper we derived a geometric characterization for solvability of the DDEP. This required a rigorous definition and the characterization of existence of (asymptotic) partial state observers. It turned out that the respective observer design is new even if the plant is governed by an ODE, since partial state observers are DAE systems in general. In the case of full state estimation also algebraic characterizations for the DDEP were derived.

A thorough investigation of the proof of Theorem 5.1 reveals that the freedom of choice in the (partial state) observer design (6) is not fully exploited yet, since we set \( L_y = 0 \) and \( L_z = 0 \). Hence, there is still room for additional tasks in the observer design apart from disturbance decoupling. Additional requirements on the observer, such as regularity of \( sE_0 - A_0 \) (and its index being at most one) or estimation of certain components of the disturbance vector, may use the full freedom.
Appendix A

We provide some preliminary results for the characterization of (asymptotic) partial state observers. To this end, we consider the set of homogeneous DAEs

\[ \frac{d}{dt}Ex(t) = Ax(t), \]  

where \( E, A \in \mathbb{R}^{l \times n} \), which is denoted by \( \Sigma_{l,n} \) and we write \([E, A] \in \Sigma_{l,n} \). The behavior of \([E, A] \in \Sigma_{l,n} \) is given by

\[ \mathcal{B}_{[E, A]} := \left\{ x \in \mathcal{D}_{\mathrm{loc}}^{1}(\mathbb{R} \rightarrow \mathbb{R}^{n}) \mid Ex \in \mathcal{A}'(\mathbb{R} \rightarrow \mathbb{R}^{l}) \text{ and } x \text{ satisfies (30) for almost all } t \in \mathbb{R} \right\}. \]

**Lemma A.1.** Let \( A \in \mathbb{R}^{n \times n}, C \in \mathbb{R}^{p \times n} \) and set \( \mathcal{O}(A, C) := [C^\top, A^\top C^\top, \ldots, (A^{n-1})^\top C^\top]^\top \).

Then the following two statements are equivalent:

(i) \( \forall x \in \mathcal{B}_{[E,A]} : \text{Cx}(0) = 0 \Rightarrow \text{Cx} = 0 \),

(ii) \( \ker \mathcal{O}(A, C) = \ker C \).

**Proof.**
(i)\(\Rightarrow\)(ii): By definition we have \( \ker \mathcal{O}(A, C) \subseteq \ker C \). Let \( x^0 \in \ker C \) and set \( x(t) := e^{At}x^0 \) for all \( t \in \mathbb{R} \). Then \( x \in \mathcal{B}_{[E,A]} \) and \( \text{Cx}(0) = Cx^0 = 0 \), thus (i) implies that \( Ce^{At}x^0 = 0 \) for all \( t \in \mathbb{R} \). By a classical argument, see e.g. (Trentelman et al., 2001, Sec. 3.3), we obtain \( x^0 \in \ker \mathcal{O}(A, C) \).

(ii)\(\Rightarrow\)(i): Let \( x \in \mathcal{B}_{[E,A]} \) with \( \text{Cx}(0) = 0 \). Then \( x(t) = e^{At}x(0) \) for all \( t \in \mathbb{R} \) and \( x(0) \in \ker C = \ker \mathcal{O}(A, C) \). According to (Trentelman et al., 2001, Sec. 3.3) we find \( \text{Cx}(t) = 0 \) for all \( t \in \mathbb{R} \).

Note that \( \ker \mathcal{O}(A, C) = \gamma^*_s[a,0,C] \) which motivates the following result.

**Lemma A.2.** Let \( E, A \in \mathbb{R}^{l \times n} \) and \( C \in \mathbb{R}^{p \times n} \). Then the following statements are equivalent:

(i) \( \forall x \in \mathcal{B}_{[E,A]} : \text{Cx}(0) = 0 \Rightarrow \text{Cx} = 0 \),

(ii) \( \forall x \in \mathcal{B}_{[E,A]} \cap C^\infty(\mathbb{R} \rightarrow \mathbb{R}^{n}) : \text{Cx}(0) = 0 \Rightarrow \text{Cx} = 0 \),

(iii) a) \( \gamma^*_s[a,0,0,C] = \gamma^*_s[a,0,C] \cap \ker C \),

b) \( \gamma^*_s[a,0,0] \cap \gamma^*_s[a,0,0,C] \subseteq \ker C \).

**Proof.** Utilizing (Berger & Trenn, 2013, Cor. 2.3) we may, without loss of generality, assume that the pencil \( sE - A \) is in quasi-Kronecker form, i.e.,

\[ sE - A = \begin{bmatrix}
    sE_p - A_p & 0 & 0 & 0 \\
    0 & sI_{n_p} - J & 0 & 0 \\
    0 & 0 & sN - I_{n_q} & 0 \\
    0 & 0 & 0 & sE_Q - A_Q
\end{bmatrix}, \]  

where

1. \( E_p, A_p \in \mathbb{R}^{l_p \times n_p}, l_p > n_p \), are such that \( \text{rk}(\lambda E_p - A_p) = n_p \) and \( \text{rk} E_p = n_p \);
2. \( J \in \mathbb{R}^{n_p \times n_p} \);
3. \( N \in \mathbb{R}^{n_{n_q} \times n_{n_q}} \) is nilpotent;
4. \( E_Q, A_Q \in \mathbb{R}^{l_Q \times n_Q}, l_Q < n_Q \), are such that \( \text{rk}(\lambda E_Q - A_Q) = l_Q \) and \( \text{rk} E_Q = l_Q \).

Let \( C = [C_1, C_2, C_3, C_4] \) according to the partitioning of \( sE - A \) in (31). Then we have that,
Proof. Let $A$.

Lemma A.3. servers.

Now, let $x \in C_0^{\infty}(\mathbb{R} \to \mathbb{R}^{\mathbb{N}^p})$ such that $x_1(0) = 0$, $E_P x_1 = A_P x_1$ and $C_1 x_1 \neq 0$. Then $x = (x_1, 0, 0, 0)^T \in C_0^{\infty}(\mathbb{R} \to \mathbb{R}^{\mathbb{N}^p})$ with $C_0(0) = 0$ and $C_0 \neq 0$, a contradiction. Therefore, we have $C_1 = 0$ and it follows from (32) that

\[
\gamma^*_{[E, A, 0, 0]} \cap \gamma^*_{[E, A, 0, 0]} = \mathbb{R}^{\mathbb{N}^p} \times \{0\} \times \{0\} \subseteq \ker[C_2, C_3, C_4] = \ker C,
\]

which proves b). Furthermore, it follows from (32) that

\[
\gamma^*_{[E, A, 0, 0]} \cap \gamma^*_{[E, A, 0, 0]} = \mathbb{R}^{\mathbb{N}^p} \times \{0\} \times \{0\} \subseteq \ker[C_2, C_3, C_4],
\]

which implies $C_1 = 0$. Furthermore, as in “(i)⇒(iii)” we have

\[
\mathbb{R}^{\mathbb{N}^p} \times \gamma^*_{[J, J, 0, C_2]} \times \{0\} \times \{0\} = \gamma^*_{[E, A, 0, 0]} \cap \ker C = \mathbb{R}^{\mathbb{N}^p} \times \ker C \times \{0\} \times \{0\},
\]

which gives $\gamma^*_{[J, J, 0, C_2]} = \ker C$. Now, let $x = (x_1, x_2, x_3, x_4)^T \in C_0^{\infty}(\mathbb{R} \to \mathbb{R}^{\mathbb{N}^p})$ with $C_0(0) = 0$. First, it follows from (Berger & Trenn, 2012, Thm. 3.2) that $x_3 \overset{a.e.}{=} 0$ and $x_4 \overset{a.e.}{=} 0$. By $C_1 = 0$ it follows $C_2 x_2(0) = 0$ and as $x_2 \in C_0^{\infty}(\mathbb{R} \to \mathbb{R}^{\mathbb{N}^p})$ and $\gamma^*_{[J, J, 0, C_2]} = \ker C_2$, we may infer from Lemma A.1 that $C_2 x_2(0) = 0$, thus $C_0 \overset{a.e.}{=} 0$.

The proof for “(ii)⇒(iii)” is analogous and omitted.

The next two results are the basis for the characterization of asymptotic partial state observers.

**Lemma A.3.** Let $A \in \mathbb{R}^{n \times n}$ and $C \in \mathbb{R}^{p \times n}$. Then the following two statements are equivalent:

(i) $\forall x \in \mathcal{B}_{[A]} : \lim_{t \to \infty} C(x(t)) = 0$,

(ii) $\forall \lambda \in \mathbb{T}_+ : \ker[C(\lambda I - A)^n] \subseteq \ker[C]$.

**Proof.** (i)⇒(ii): Seeking a contradiction we assume that there exist $\lambda \in \mathbb{T}_+$ and $x^0 \in \ker[C(\lambda I - A)^n] \neq 0$. Obviously, $\lambda$ is an eigenvalue of $A$. By (Logemann & Ryan, 2014, Thm. 2.11) we find that

\[
e^{A t} x^0 = \sum_{i=0}^{m-1} \frac{t^i}{i!} (A - \lambda I)^i x^0, \quad t \in \mathbb{R},
\]
where \( m \) is the algebraic multiplicity of \( \lambda \). Let \( k \in \{0, \ldots, p\} \) such that \( e_k^t C x^0 \neq 0 \), where \( e_k \) denotes the \( k \)th unit vector. Invoking that for any polynomial \( p(t) = a_0 + a_1 t + \ldots + a_d t^d \) with \( a_0 \neq 0 \) it holds \( |p(t)| \geq |a_0| \) for sufficiently large \( t \), we may infer that there exists \( T > 0 \) such that for all \( t \geq T \) we have

\[
C x(t) = C x(0) = \sum_{j=1}^r e^{\lambda_j t} \sum_{i=0}^{m_j-1} \frac{t^i}{i!} (A-\lambda_j I) z_j, \quad t \in \mathbb{R},
\]

where \( m_j \) is the algebraic multiplicity of \( \lambda_j \) and \( z_j \in \ker C (A-\lambda_j I)^m_j \) for \( j = 1, \ldots, r \). We may assume that \( \lambda_1, \ldots, \lambda_q \in \mathbb{C}_+ \) and \( \lambda_{q+1}, \ldots, \lambda_r \in \mathbb{C}_- \) for some \( q \in \{0, \ldots, r\} \). Since \( (A-\lambda_j I)^m_j z_j \in \ker C (A-\lambda_j I)^n \subseteq \ker C \) for all \( j = 1, \ldots, q \) it follows that

\[
C x(t) = \sum_{j=q+1}^r e^{\lambda_j t} \sum_{i=0}^{m_j-1} \frac{t^i}{i!} C (A-\lambda_j I)^i z_j, \quad t \in \mathbb{R},
\]

and hence, obviously, \( C x(t) \to 0 \) which completes the proof.

In the following DAE version we use the space \( \mathcal{W}^{\alpha}_{[E, A], \lambda} \) introduced in Section 2.

**Lemma A.4.** Let \( E, A \in \mathbb{R}^{l \times n} \) and \( C \in \mathbb{R}^{p \times n} \). Then the following statements are equivalent:

(i) \( \forall x \in \mathcal{B}_{[E, A]} : \lim_{t \to \infty} \sup_{t \geq 0} \| C x(t) \| = 0 \).

(ii) \( \forall x \in \mathcal{B}_{[E, A]} \cap \mathcal{C}^\infty_0 (\mathbb{R} \to \mathbb{R}^n) : \lim_{t \to \infty} C x(t) = 0 \).

(iii) \( \forall \lambda \in \mathbb{C}_+ : \mathcal{W}^{\alpha}_{[E, A], \lambda} \subseteq \ker C \).

**Proof.** Without loss of generality we assume that \( s E - A \) is in quasi-Kronecker form (31) with the properties stated in the proof of Lemma A.2, and \( C = [C_1, C_2, C_3, C_4] \) according to the partitioning of \( s E - A \). It is a straightforward calculation, see also Berger and Trenn (2013), that

\[
\mathcal{W}^{\alpha}_{[E, A], \lambda} = \mathbb{C}^{mp} \times \ker C (\lambda I - J)^n \times \{0\} \times \{0\}. \tag{33}
\]

(i)\(\Rightarrow\)(iii): We show that \( C_1 \equiv 0 \). Assume that \( C_1 \neq 0 \) and choose \( x_1 \in \mathcal{C}^\infty_0 (\mathbb{R} \to \mathbb{R}^p) \) such that \( E_1 x_1 = A_1 x_1 \) and \( \| C_1 x_1(t) \| \to \infty \). Then \( x = (x_1^T, 0, 0)^T \in \mathcal{B}_{[E, A]} \) with \( C x \not\to 0 \), a contradiction. Therefore, \( C_1 \equiv 0 \) and, in view of (33), it remains to show that for all \( \lambda \in \mathbb{C}_+ \) we have \( \ker C (\lambda I - J)^n \subseteq \ker C 2 \). This follows from Lemma A.3 and the fact that for any \( x_2 \in \mathcal{B}_{[I, J]} \) we have that \( x = (0, x_2^T, 0, 0)^T \in \mathcal{B}_{[E, A]} \) and hence \( C_2 x_2(t) \equiv C x(t) \to 0 \).

(iii)\(\Rightarrow\)(i): By (33) we obtain \( C_1 \equiv 0 \) and hence \( \ker C (\lambda I - J)^n \subseteq \ker C 2 \) for all \( \lambda \in \mathbb{C}_+ \). Therefore, Lemma A.3 implies that for all \( x_2 \in \mathcal{B}_{[I, J]} \) we have \( C_2 x_2(t) \to 0 \). If now \( x = (x_1^T, x_2^T, x_3^T, x_4^T)^T \in \mathcal{B}_{[E, A]} \), then it follows from (Berger & Trenn, 2012, Thm. 3.2) that \( x_{a, e} \equiv 0 \)
and $x_4 \equiv 0$. Furthermore, $x_2 \in \mathcal{B}_{[I, J]}$ and therefore we obtain

$$\lim_{t \to \infty} \text{ess sup}_{[t, \infty)} \|Cx(t)\| = \lim_{t \to \infty} \text{ess sup}_{[t, \infty)} \|C_2x_2(t)\| = 0.$$  

The proof for “(ii) $\Leftrightarrow$ (iii)” is analogous and omitted.
