

Line Bundle Gerbes from 2-Transport

September 7, 2006

Abstract

The concept of a line bundle gerbe with connection and curving is a special case of transition data of 2-transport.

Our main aim is to prove theorem 1.

Before doing so, we motivate the discussion by some considerations concerning associated 2-bundles.

Let

$$\rho : \Sigma(G_2) \rightarrow T' \subset \text{Mod}_{\mathcal{C}}$$

be a faithful representation of the 2-group G_2 and

$$T' \xrightarrow{i} T$$

some monomorphism. Then we say that tra is a **associated \mathcal{C} -vector transport** with respect to (ρ, i) if it admits a proper trivialization

$$\begin{array}{ccc}
 \mathcal{P}_U & \xrightarrow{p} & \mathcal{P} \\
 \text{tra}^i \downarrow & \swarrow t \sim & \downarrow \text{tra} \\
 G_2 & \xrightarrow{\rho} T' \xrightarrow{i} T &
 \end{array}$$

Some familiar associated 2-bundles come from the following class of representations of 2-groups.

Proposition 1 *For any strict 2-group $G_2 = (H \rightarrow G)$, a representation $\rho : \Sigma(H) \rightarrow \mathbf{Vect}_K$ of H for which the family $\{\rho(h) \mid h \in H\}$ is linearly independent over K induces a representation*

$$\tilde{\rho} : \Sigma(G_2) \rightarrow \text{Bim}(\mathbf{Vect}) \xrightarrow{i} \text{Mod}_{\mathbf{Vect}}$$

given by

$$\tilde{\rho} : \Sigma(G_2) \rightarrow \mathbf{Bim}(\mathbf{Vect})$$

Here

$$A_\rho \equiv \langle \rho(h) \mid h \in H \rangle$$

is the algebra generated by the endomorphisms representing H and (A_ρ, g) is A_ρ regarded as a bimodule over itself, with the right action twisted by the automorphism g .

Proof. Let

$$\rho : \Sigma(H) \rightarrow \mathbf{Vect}$$

and notice that the notation for composition is such that

$$V \xrightarrow{\rho(hh')} V = \rho \left(\bullet \xrightarrow{h} \bullet \xrightarrow{h'} \bullet \right) = V \xrightarrow{\rho(h)} V \xrightarrow{\rho(h')} V = V \xrightarrow{\rho(h') \circ \rho(h)} V .$$

Also recall that 2-morphisms in $\Sigma(G_2)$

are labeled by $g \in G$ and $h \in H$ with

for arbitrary $f \in H$. What we shall need below is the commutativity of the image of this diagram under ρ

$$\begin{array}{ccc} V & \xrightarrow{\rho(h)} & V \\ \rho(g'(f)) \downarrow & & \downarrow \rho(g(f)) \\ V & \xrightarrow{\rho(h)} & V \end{array} . \quad (1)$$

In order to construct $\tilde{\rho}$ let now

$$\text{End}_V \supset A_\rho \equiv \langle \rho(h) \mid h \in H \rangle$$

be the subalgebra of the endomorphism algebra of V which is generated by the linear maps $\rho(h)$ for all $h \in H$. We obtain for each $g \in \text{Aut}(H)$ an automorphism $\rho(g) \in \text{Aut}(A_\rho)$ of this algebra by setting

$$\rho(g) : \rho(h) \mapsto \rho(g(h))$$

for all $h \in H$, and extended linearly to all of A_ρ .

Using this, for each $g \in G$ we define an A_ρ -bimodule

$$(A_\rho, g) \equiv A_\rho - \overset{\text{Id}}{\rhd} A_\rho \leftarrow \overset{\rho(g)}{\lhd} A_\rho$$

which, as an object in **Vect**, is A_ρ itself, with both the right and the left A_ρ action given by the product in A_ρ , but with the right action twisted by $\rho(g)$:

$$\begin{aligned} \rho(h) \cdot a &\equiv \rho(h) \circ a \\ a \cdot \rho(h) &\equiv a \circ \rho(g(h)) . \end{aligned} \quad (2)$$

for all $a \in A_\rho$.

The tensor product over A_ρ corresponds to the composition of automorphisms

$$(A_\rho, g) \otimes_{A_\rho} (A_\rho, g') = (A_\rho, gg') ,$$

which shows that $\tilde{\rho}$ is properly functorial on the level of 1-morphisms. For each 2-morphism

define a morphism of bimodules

$$\begin{aligned} \tilde{\rho}(h) : (A_\rho, g) &\rightarrow (A_\rho, g') \\ a &\mapsto a \circ \rho(h) . \end{aligned}$$

This map trivially respects the left A_ρ -action. That it also respects the right A_ρ action is a consequence of the commutativity of (1):

$$\begin{array}{ccc}
 (a, \rho(f)) & \xrightarrow{\tilde{\rho}(h) \times \text{Id}} & (a \circ \rho(h), \rho(f)) \\
 \downarrow (2) & & \downarrow (2) \\
 & & a \circ \rho(h) \circ \rho(g'(f)) \\
 & & \parallel (1) \\
 a \circ \rho(g(f)) & \xrightarrow{\tilde{\rho}(h)} & a \circ \rho(g(f)) \circ \rho(h)
 \end{array}$$

That $\tilde{\rho}$ defined this way is functorial for vertical composition follows from

$$\tilde{\rho} \left(\begin{array}{c} \bullet \xrightarrow{g} \bullet \\ \Downarrow h'h \\ \bullet \xrightarrow{g''} \bullet \end{array} \right) = \tilde{\rho} \left(\begin{array}{c} \bullet \xrightarrow{g} \bullet \\ \Downarrow h \\ \bullet \xrightarrow{g'} \bullet \\ \Downarrow h' \\ \bullet \xrightarrow{g''} \bullet \end{array} \right) = V \begin{array}{c} \xrightarrow{(A_\rho, g)} \\ \Downarrow \circ \rho(h) \\ \xrightarrow{(A_\rho, g')} \\ \Downarrow \circ \rho(h') \\ \xrightarrow{(A_\rho, g'')} \end{array} V = V \begin{array}{c} \xrightarrow{(A_\rho, g)} \\ \Downarrow \rho(h'h) \\ \xrightarrow{(A_\rho, g'')} \end{array} V,$$

by our remark above. Finally, the 2-functoriality of $\tilde{\rho}$ requires that

$$\begin{aligned}
 \tilde{\rho} \left(\begin{array}{c} \bullet \xrightarrow{gg'} \bullet \\ \Downarrow g(h) \\ \bullet \xrightarrow{gt(h)g'} \bullet \end{array} \right) &= \tilde{\rho} \left(\begin{array}{c} \bullet \xrightarrow{g} \bullet \xrightarrow{g'} \bullet \\ \Downarrow h \\ \bullet \xrightarrow{t(h)} \bullet \end{array} \right) \\
 &= A_\rho \xrightarrow{(A_\rho, g)} A_\rho \begin{array}{c} \xrightarrow{(A_\rho, \text{Id})} \\ \Downarrow \circ \rho(h) \\ \xrightarrow{(A_\rho, g')} \end{array} A_\rho \xrightarrow{(A_\rho, g')} A_\rho.
 \end{aligned}$$

This can be checked for instance by representing elements of $(A_\rho, g) \otimes_{A_\rho} (A_\rho, \text{Id})$ by $(a, \text{Id}) \in A_\rho \times A_\rho$. Then in particular $\tilde{\rho}(h)((a, \text{Id})) = (a, \text{Id} \circ \rho(h)) \sim (a \circ \rho(g(h)), \text{Id})$. \square

Example 1

Let G_2 be the automorphism 2-group of $\Sigma(U(1))$ $G_2 = (U(1) \rightarrow \mathbb{Z}_2)$. Let $\rho : \Sigma(U(1)) \rightarrow \mathbf{Vect}_{\mathbb{R}}$ be the defining 2 real dimensional representation.

In this case we find $A_\rho \simeq \mathbb{C}$, the complex numbers, regarded as an \mathbb{R} -algebra. The bimodule (A_ρ, Id) is just \mathbb{C} itself, with the left and right \mathbb{C} -action given by multiplication of complex numbers.

$$(A_\rho, \text{Id}) = \mathbb{C}.$$

Denote the nontrivial element of \mathbb{Z}_2 by σ . The bimodule (A_ρ, σ) is, as an object, \mathbb{C} , with the left \mathbb{C} -action given by multiplication of complex numbers and the right \mathbb{C} -action given by conjugation followed by multiplication. We write

$$(A_\rho, \sigma) \equiv \mathbb{C}_\sigma.$$

Concretely, the left and right actions on \mathbb{C}_σ are

$$\begin{array}{ccc} \mathbb{C} \times \mathbb{C}_\sigma & \xrightarrow{l} & \mathbb{C}_\sigma \\ (c, d) & \mapsto & cd \end{array}$$

and

$$\begin{array}{ccc} \mathbb{C}_\sigma \times \mathbb{C} & \xrightarrow{r} & \mathbb{C}_\sigma \\ (d, c) & \mapsto & \bar{c}d \end{array}.$$

Similarly, for any complex vector space V , let

$$V_\sigma \simeq V \otimes \mathbb{C}_\sigma$$

and

$${}_\sigma V \simeq \mathbb{C}_\sigma \otimes V$$

be the \mathbb{C} - \mathbb{C} -bimodule V , as an object, but with the left or right \mathbb{C} action twisted, as indicated.

Notice that we have the canonical isomorphism

$${}_\sigma V_\sigma \simeq \bar{V},$$

where \bar{V} is V equipped with the opposite complex structure, and hence in particular the canonical identification

$$\mathbb{C}_\sigma \otimes \mathbb{C}_\sigma \simeq \bar{\mathbb{C}} \simeq \mathbb{C}.$$

Denote by $\text{Bim}_{\mathbb{C}}$ the 2-category of \mathbb{C} - \mathbb{C} -bimodules, with single object \mathbb{C} , bimodules up to canonical isomorphism as 1-morphisms and bimodule intertwiners as 2-morphisms.

We write

$$\begin{array}{c} \begin{array}{ccc} \bullet & \begin{array}{c} \curvearrowright \\ V \\ \curvearrowleft \\ \Downarrow \bar{\phi} \end{array} & \bullet \\ & & \end{array} \quad \equiv \quad \begin{array}{ccc} \bullet & \begin{array}{c} \xrightarrow{\mathbb{C}_\sigma} \bullet \\ \curvearrowright \\ V \\ \curvearrowleft \\ \Downarrow \phi \\ \bullet \\ \xrightarrow{\mathbb{C}_\sigma} \bullet \end{array} & \bullet \end{array} \end{array}$$

and find in particular

$$\bullet \xrightarrow{\mathbb{C}_\sigma} \bullet \begin{array}{c} \curvearrowright \\ \Downarrow c \\ \curvearrowleft \end{array} \bullet \xrightarrow{\mathbb{C}_\sigma} \bullet = \bullet \begin{array}{c} \curvearrowright \\ \Downarrow \bar{c} \\ \curvearrowleft \end{array} \bullet .$$

It follows that we get an involutive inner automorphism

$$\text{Bim}_{\mathbb{C}} \xrightarrow{\text{Ad}_{\mathbb{C}_\sigma}} \text{Bim}_{\mathbb{C}}$$

given by conjugation with \mathbb{C}_σ as

$$s : \bullet \begin{array}{c} \curvearrowright \\ \Downarrow \phi \\ \curvearrowleft \end{array} \bullet \mapsto \bullet \xrightarrow{\mathbb{C}_\sigma} \bullet \begin{array}{c} \curvearrowright \\ \Downarrow \phi \\ \curvearrowleft \end{array} \bullet \xrightarrow{\mathbb{C}_\sigma} \bullet .$$

Given any transport

$$\text{tra} : \mathcal{P} \rightarrow \text{Bim}_{\mathbb{C}}$$

we hence obtain what could be called the “opposite” transport

$$\text{tra}^{\text{op}} \equiv (\text{Ad}_{\mathbb{C}_\sigma})^* \text{tra} : \mathcal{P} \xrightarrow{\text{tra}} \text{Bim}_{\mathbb{C}} \xrightarrow{\text{Ad}_{\mathbb{C}_\sigma}} \text{Bim}_{\mathbb{C}} .$$

We will be interested in transition morphisms in $\mathbf{Trans}(\mathcal{P}, \text{Bim}_{\mathbb{C}})$. Consider the case where such a morphism involves \mathbb{C}_σ in its defining tin can equation as follows

$$\begin{array}{ccc} \bullet & & \bullet \\ p_{12}^* L \swarrow & \Downarrow f & \searrow p_{23}^* L \\ \bullet & \xrightarrow{p_{13}^* L} & \bullet \\ \downarrow \mathbb{C}_\sigma & \Downarrow \text{Id} & \downarrow \mathbb{C}_\sigma \\ \bullet & \xrightarrow{p_{13}^* L'} & \bullet \end{array} = \begin{array}{ccc} \bullet & & \bullet \\ p_{12}^* L \swarrow & \downarrow \mathbb{C}_\sigma & \searrow p_{23}^* L \\ \bullet & \Downarrow \text{Id} & \bullet \\ \downarrow \mathbb{C}_\sigma & \swarrow p_{12}^* L' & \searrow p_{23}^* L' \\ \bullet & \xrightarrow{p_{13}^* L'} & \bullet \end{array} .$$

The existence of the identity-2-morphisms here says that the transition lines are related by $L' = \bar{L}$.

This equation can equivalently be rewritten as

$$\begin{array}{ccc} \bullet & & \bullet \\ p_{12}^* L' \swarrow & \Downarrow f' & \searrow p_{23}^* L' \\ \bullet & \xrightarrow{p_{13}^* L'} & \bullet \end{array} = \begin{array}{ccc} \bullet & & \bullet \\ p_{12}^* L \swarrow & \Downarrow f & \searrow p_{23}^* L \\ \bullet & \xrightarrow{p_{13}^* L} & \bullet \\ \downarrow \mathbb{C}_\sigma & & \downarrow \mathbb{C}_\sigma \end{array} ,$$

which says that

$$f' = \bar{f}.$$

Example 2

$$G_2 = (U(n) \rightarrow PU(n))$$

$$\rho : U(n) \rightarrow \mathbb{C}^n$$

$$PU(n) = \{[g] | g \in U(n)\}$$

$$A_\rho = \text{End}_{\mathbb{C}^n}$$

$$\begin{aligned} (A_\rho, [g]) \times A_\rho &\rightarrow \mathbb{C}^n \\ (a, b) &\mapsto a \circ \rho(g)^{-1} \circ b \circ \rho(g) \end{aligned}$$

Example 3

Let $A \rightarrow X$ be an algebra bundle with typical fiber $\text{End}_{\mathbb{C}^n}$. Let ∇ be a connection on E and let $\text{tra}_\nabla : \mathcal{P}_1(X) \rightarrow \text{Trans}(A)$ be the corresponding parallel transport. The automorphism group of $\text{End}_{\mathbb{C}^n}$ is $PU(n)$, hence A is an associated $PU(n)$ -bundle.

Define a 2-transport

$$\text{tra}_{(A, \nabla)} : \mathcal{P}_2(X) \rightarrow \text{Bim}(\mathbf{Vect})$$

by

$$\text{tra}_{(A, \nabla)} : \begin{array}{ccc} & \xrightarrow{\gamma_1} & \\ x & \Downarrow S & y \\ & \xleftarrow{\gamma_2} & \end{array} \mapsto \begin{array}{ccc} & \xrightarrow{(A_x, \text{tra}_\nabla(\gamma_1))} & \\ A_x & \Downarrow f(S) & A_y \\ & \xrightarrow{(A_x, \text{tra}_\nabla(\gamma_2))} & \end{array},$$

where $f(S)$ is the unique lift of $\text{tra}_\nabla(\bar{\gamma}_1) \circ \text{tra}_\nabla(\gamma_2)$ to A_x such that

$$\exp\left(n \int_S B\right) = \det(f(S)).$$

In order to see that this assignment is indeed 2-functorial, choose a basis $A_x \xrightarrow{t(x)} \text{End}_{\mathbb{C}^n}$ for all endpoints involved in the computation. Then use the logic of example 2.

Diagrammatically, we would naturally associate to each surface

$$\begin{array}{ccc} & \xrightarrow{\gamma_1} & \\ x & \Downarrow S & y \\ & \xleftarrow{\gamma_2} & \end{array}$$

the 2-cell

In terms of string diagrams the right hand side reads

This can be seen to be almost the same bimodule homomorphism as above, up to a scalar multiple. Where before we had the determinant, this involves a trace. As a result, this second assignment is not 2-functorial in general.

Proposition 2 *The 2-transport from example 3 is an associated \mathbf{Vect} -vector transport with respect to*

$$(U(1) \rightarrow \mathbb{Z}_2) \xrightarrow{\tilde{\rho}} \mathbf{Bim}_{\mathbb{C}} \xrightarrow{i} \mathbf{Bim}(\mathbf{Vect}) ,$$

with $\tilde{\rho}$ the representation from example 1.

Proof.

Locally we may always identify, $A|_U \xrightarrow{\tau} \text{End}_V$, the bundle A with the endomorphism bundle of some vector bundle V with connection tra_V . This can

be expressed in terms of bimodules as

$$\begin{array}{ccc}
 A_x & \xrightarrow{(A_x, \text{tra}_\nabla(\gamma))} & A_y \\
 (A_x, \tau(x)) \downarrow & \swarrow \text{Id} & \downarrow (A_y, \tau(y)) \\
 \text{End}_{V_x} & \xrightarrow{(\text{End}_{V_x}, \text{Ad}_{\text{tra}_V(\gamma)})} & \text{End}_{V_y}
 \end{array} .$$

Consider the bimodule homomorphisms

$$\begin{array}{ccc}
 \text{End}_{V_x} & \xrightarrow{(\text{End}_x, \text{Ad}_{\text{tra}_V(\gamma)})} & \text{End}_{V_y} \\
 V_x \downarrow & \swarrow \text{tra}_V(\gamma) & \downarrow V_y \\
 \mathbb{C} & \xrightarrow{\mathbb{C}} & \mathbb{C}
 \end{array}$$

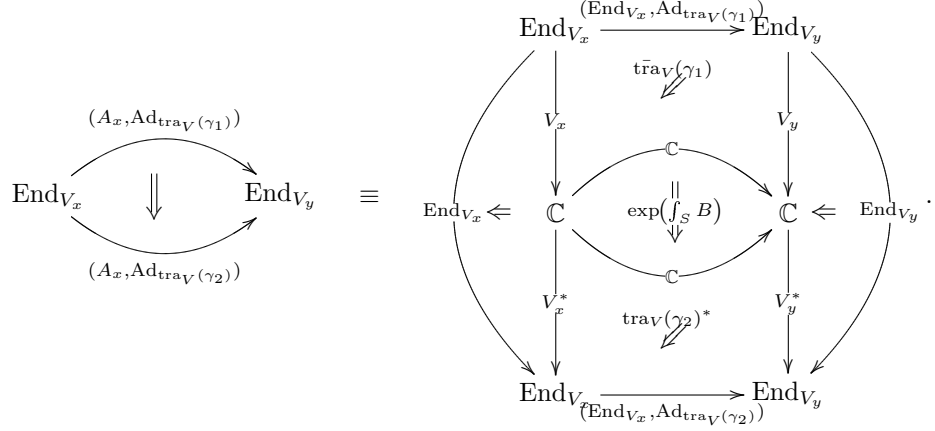

and

$$\begin{array}{ccc}
 \mathbb{C} & \xrightarrow{\mathbb{C}} & \mathbb{C} \\
 V_x^* \downarrow & \swarrow \text{tra}_V^*(\gamma) & \downarrow V_y^* \\
 \text{End}_{V_x} & \xrightarrow{(\text{End}_x, \text{Ad}_{\text{tra}_V(\gamma)})} & \text{End}_{V_y}
 \end{array} .$$

These fit into an adjoint equivalence due to

$$\begin{array}{ccc}
 \text{End}_{V_x} \xrightarrow{(\text{End}_x \otimes W_\gamma, \text{tra}_1)} \text{End}_{V_y} & & \text{End}_{V_x} \xrightarrow{(\text{End}_x \otimes W_\gamma, \text{tra}_1)} \text{End}_{V_y} \\
 V_x \downarrow \quad \swarrow \text{tra}_1(\gamma) \quad \downarrow V_y & & \downarrow V_x \quad \swarrow \text{Id} \quad \downarrow \text{End}_{V_y} \\
 \mathbb{C} \xrightarrow{W_\gamma} \mathbb{C} \Leftarrow \text{End}_{V_y} & = & \mathbb{C} \Leftarrow \text{End}_{V_x} \quad \swarrow \text{Id} \quad \text{End}_{V_y} \\
 V_x^* \downarrow \quad \swarrow \text{tra}_1^*(\gamma) \quad \downarrow V_y^* & & \downarrow V_x^* \quad \swarrow \text{Id} \quad \downarrow \text{End}_{V_y} \\
 \text{End}_{V_x} \xrightarrow{(\text{End}_x \otimes W_\gamma, \text{tra}_1)} \text{End}_{V_y} & & \text{End}_{V_x} \xrightarrow{(\text{End}_x \otimes W_\gamma, \text{tra}_1)} \text{End}_{V_y}
 \end{array} .$$

Therefore, given a 2-form $B \in \Omega^2(U)$, we can form the 2-transport

The composition of 2-cells on the right corresponds to the bimodule homomorphism which sends $a \in \text{End}_{V_x}$ to

$$\begin{aligned}
& \left(V_x \xrightarrow{a} V_x \right) \\
\mapsto & \left(\sum_i V_y \xrightarrow{e^i} \mathbb{C} \xrightarrow{e_i} V_y \xrightarrow{\bar{\text{trav}}_V(\gamma_1)} V_x \xrightarrow{a} V_x \xrightarrow{\text{trav}_V(\gamma_2)} V_y \right) \\
\mapsto & \exp\left(\int_S B\right) \left(\sum_i V_x \xrightarrow{\text{trav}_V(\gamma_2)} V_y \xrightarrow{e^i} \mathbb{C} \xrightarrow{e_i} V_y \xrightarrow{\bar{\text{trav}}_V(\gamma_1)} V_x \xrightarrow{a} V_x \xrightarrow{\text{trav}_V(\gamma_1)} V_y \xrightarrow{\bar{\text{trav}}_V(\gamma_1)} V_x \right) \\
\mapsto & \exp\left(\int_S B\right) \left(\sum_i V_x \xrightarrow{\text{trav}_V(\gamma_2)} V_y \xrightarrow{\bar{\text{trav}}_V(\gamma_1)} V_x \xrightarrow{a} V_x \right),
\end{aligned}$$

hence to $a \circ \bar{\text{trav}}_V(\gamma_1) \circ \text{trav}_V(\gamma_2)$, up to a scalar factor. This is indeed, locally, the assignment of the 2-transport from example 3. We re-obtain the global

2-transport by pulling this back along τ

$$\begin{array}{c}
 \begin{array}{ccc}
 A_x & \xrightarrow{(A_x, \text{tra}_\nabla(\gamma))} & A_y \\
 \downarrow (A_x, \tau(x)) & \swarrow \text{Id} & \downarrow (A_y, \tau(y)) \\
 \text{End}_{V_x} & \xrightarrow{(\text{End}_{V_x}, \text{Ad}_{\text{tra}_V(\gamma_1)})} & \text{End}_{V_y} \\
 \downarrow V_x & \swarrow \bar{\text{tra}}_V(\gamma_1) & \downarrow V_y \\
 \mathbb{C} & \xrightarrow{\exp(\int_S B)} & \mathbb{C} \\
 \downarrow V_x^* & \swarrow \text{tra}_V(\gamma_2)^* & \downarrow V_y^* \\
 \text{End}_V & \xrightarrow{(\text{End}_V, \text{Ad}_{\text{tra}_V(\gamma_2)})} & \text{End}_V \\
 \downarrow (\text{End}_V, \bar{\tau}(x)) & \swarrow \text{Id} & \downarrow (\text{End}_V, \bar{\tau}(y)) \\
 A_x & \xrightarrow{(A_x, \text{tra}_\nabla(\gamma_2))} & A_y
 \end{array} \\
 = \\
 \begin{array}{ccc}
 A_x & \xrightarrow{(A_x, \text{tra}_\nabla(\gamma_1))} & A_y \\
 \downarrow f(S) & & \downarrow f(S) \\
 A_x & \xrightarrow{(A_x, \text{tra}_\nabla(\gamma_2))} & A_y
 \end{array}
 \end{array}$$

□

Proposition 3 *The transitions of the local trivialization from prop. 2 are i -transitions, for the obvious embedding $i : \Sigma(\Sigma(\mathbb{C})) \longrightarrow \Sigma(1\text{DVect}_{\mathbb{C}})$.*

This motivates the study of $\text{Tra}(i)$, the 2-category of i -transitions. Let $p : Y \rightarrow X$ be a surjective submersion.

Theorem 1 *The 2-category of $(\mathcal{P}_2(Y) \xrightarrow{p} \mathcal{P}_2(X))$ -local $(\Sigma(\mathbb{C}) \xrightarrow{i} 1\text{DVect}_{\mathbb{C}})$ -transitions is equivalent (isomorphic, even) to the 2-category of line bundle gerbes for fixed Y*

$$\text{Tra}(p, i) \simeq \text{BunGer}(Y) .$$

We prove this using a couple of lemmas.

Lemma 1 *Let $\text{tra} : \mathcal{P}_2 \rightarrow \Sigma(1\text{DVect})$ be a 2-transport which assigns 1-dimensional vector spaces to paths and linear maps to surfaces.*

1. 1-Automorphisms $\text{tra} \xrightarrow{\sim} \text{tra}$ are in bijection with flat transport $\mathcal{P}_1 \rightarrow 1\text{DVect}$, i.e. with flat line bundle with connection.
2. Composition of these 1-automorphisms corresponds to taking the tensor product of the corresponding line bundles.

3. 2-morphisms between these 1-automorphisms correspond to natural transformations of the transport 1-functors of the corresponding line bundles and hence to isomorphisms between these line bundles which fix the base space.

Proof.

1. Write $V = \text{tra}(\gamma)$ for the vector space associated by tra to $x \xrightarrow{\gamma} y$. Then

$$\begin{array}{ccc}
 \bullet & \xrightarrow{\text{tra}(\gamma)} & \bullet \\
 \downarrow \phi(x) & \searrow \phi(\gamma) & \downarrow \phi(y) \\
 \bullet & \xrightarrow{\text{tra}(\gamma)} & \bullet
 \end{array}$$

is a linear map

$$V \otimes \phi(y) \xrightarrow{\phi(\gamma)} \phi(x) \otimes V.$$

Since V is 1-dimensional this defines a linear map

$$\phi(y) \xrightarrow{\phi(\gamma)} \phi(x)$$

under the isomorphism

$$\begin{aligned}
 \text{Hom}(V \otimes \phi(y), \phi(x) \otimes V) &\simeq \text{Hom}(\phi(y), V^* \otimes \phi(x) \otimes V) \\
 &\simeq \text{Hom}(\phi(y), \phi(x) \otimes V^* \otimes V) \\
 &\simeq \text{Hom}(\phi(y), \phi(x) \otimes K) \\
 &\simeq \text{Hom}(\phi(y), \phi(x)).
 \end{aligned}$$

The functoriality condition on ϕ

$$\begin{array}{ccc}
 \bullet & \xrightarrow{\text{tra}(\gamma_1)} & \bullet & \xrightarrow{\text{tra}(\gamma_2)} & \bullet \\
 \downarrow \phi(x) & \searrow \phi(\gamma_1) & \downarrow \phi(y) & \searrow \phi(\gamma_2) & \downarrow \phi(z) \\
 \bullet & \xrightarrow{\text{tra}(\gamma_1)} & \bullet & \xrightarrow{\text{tra}(\gamma_2)} & \bullet
 \end{array}
 =
 \begin{array}{ccc}
 \bullet & \xrightarrow{\text{tra}(\gamma_1 \cdot \gamma_2)} & \bullet \\
 \downarrow \phi(x) & \searrow \phi(\gamma_1 \cdot \gamma_2) & \downarrow \phi(z) \\
 \bullet & \xrightarrow{\text{tra}(\gamma_1 \cdot \gamma_2)} & \bullet
 \end{array}$$

translates similarly into

$$\phi(z) \xrightarrow{\phi(\gamma_2)} \phi(y) \xrightarrow{\phi(\gamma_1)} \phi(x) = \phi(z) \xrightarrow{\phi(\gamma_1 \cdot \gamma_2)} \phi(x).$$

Therefore $\bar{\phi}$ defines a functor

$$\bar{\phi} : \mathcal{P}_1(M) \rightarrow \mathbf{Vect}_1$$

and hence a bundle with connection on M . Finally, ϕ has to make the tin can equation hold

Since we have the same $x \begin{array}{c} \xrightarrow{\gamma_1} \\ \Downarrow S \\ \xrightarrow{\gamma_2} \end{array} y$ on both sides this implies that

$$\phi(\gamma_1) = \phi(\gamma_2) .$$

Hence ϕ is *flat*. Running these arguments backwards shows that conversely every flat line bundle on M gives rise to an automorphism $\text{tra} \xrightarrow{\phi} \text{tra} \cdot$

2. The composition

corresponds to

$$\begin{array}{ccc} \phi(x) & \phi_1(x) \otimes \phi_2(x) \\ \bar{\phi}(\gamma) \downarrow & = \quad \bar{\phi}_1(\gamma) \otimes \bar{\phi}_2(\gamma) \downarrow \\ \phi(y) & \phi_1(y) \otimes \phi_2(y) \end{array}$$

3. A 2-morphism

$$\begin{array}{ccc}
 & \phi_1 & \\
 \text{tra} & \begin{array}{c} \curvearrowright \\ \Downarrow \mathcal{A} \\ \curvearrowleft \end{array} & \text{tra} \\
 & \phi_2 &
 \end{array}$$

satisfies the tin can equation of the following form:

$$\begin{array}{ccc}
 \bullet & \xrightarrow{\text{tra}(\gamma)} & \bullet \\
 \downarrow \phi_1(x) & \swarrow \phi_1(\gamma) & \downarrow \phi_1(y) \\
 \phi_2(x) & & \phi_2(y) \\
 \downarrow \phi_2(x) & \swarrow \phi_2(\gamma) & \downarrow \phi_2(y) \\
 \bullet & \xrightarrow{\text{tra}(\gamma)} & \bullet
 \end{array}
 =
 \begin{array}{ccc}
 \bullet & \xrightarrow{\text{tra}(\gamma)} & \bullet \\
 \downarrow \phi_2(x) & \swarrow \phi_2(\gamma) & \downarrow \phi_2(y) \\
 \phi_2(x) & & \phi_2(y) \\
 \downarrow \phi_2(x) & \swarrow \phi_2(\gamma) & \downarrow \phi_2(y) \\
 \bullet & \xrightarrow{\text{tra}(\gamma)} & \bullet
 \end{array}$$

Under the above identification of $\phi(\gamma)$ with a linear map $\bar{\phi}(x) \xrightarrow{\bar{\phi}(\gamma)} \bar{\phi}(y)$ this is equivalent to a natural transformation

$$\begin{array}{ccc}
 \phi_2(x) & \xrightarrow{\bar{\mathcal{A}}(x)} & \phi_1(x) \\
 \downarrow \bar{\phi}_1(\gamma) & & \downarrow \bar{\phi}_2(\gamma) \\
 \phi_2(y) & \xrightarrow{\bar{\mathcal{A}}(y)} & \phi_1(y)
 \end{array}$$

□

In the same way one proves

Lemma 2

1. 1-morphisms of i -trivial 2-transport are in bijection with line bundles with connection.
2. Composition of such 1-morphisms corresponds to taking the tensor product of the corresponding line bundles.
3. 2-morphisms between such 1-morphisms of trivial line-2-bundles correspond to bundle isomorphisms of the corresponding line bundles.

Lemma 3 Let $\text{tra}_B, \text{tra}_{B'} : \mathcal{P}_2 \rightarrow \Sigma 1\text{DVect}$ be i -trivial 2-transport coming from the 2-forms $B, B' \in \Omega^2(\text{Lie}(\text{U}(1)))$. Let $\text{tra}_B \xrightarrow{\text{tra}_\nabla} \text{tra}_{B'}$ be the morphism given by the line bundle with connection ∇ by lemma 2. Then

$$B' = B + F_\nabla.$$

Proof. The existence of $\text{tra}_B \xrightarrow{\text{tra}_\nabla} \text{tra}_{B'}$ is equivalent to the 2-commutativity of all respective tin cans:

This immediately implies the above statement. \square

Definition 1 (Murray) A line bundle gerbe over a manifold M is

- a surjective submersion

- a \mathbb{C}^\times -bundle

- over $Y^{[3]} \begin{matrix} \xrightarrow{p_{12}} \\ \xrightarrow{p_{13}} \\ \xrightarrow{p_{23}} \end{matrix} Y^{[2]}$ a bundle isomorphism

$$p_{12}^* L \otimes p_{23}^* L \xrightarrow{f} p_{13}^* L$$

which is associative in the sense that on $Y^{[4]} \begin{matrix} \xrightarrow{p_{123}} \\ \xrightarrow{p_{124}} \\ \xrightarrow{p_{134}} \\ \xrightarrow{p_{234}} \end{matrix} Y^{[3]}$ the diagram

$$\begin{array}{ccc} p_{12}^* L \otimes p_{23}^* L \otimes p_{34}^* L & \xrightarrow{p_{123}^* f \otimes \text{Id}} & p_{13}^* L \otimes p_{34}^* L \\ \text{Id} \otimes p_{234}^* f \downarrow & & \downarrow p_{134}^* f \\ p_{12}^* L \otimes p_{24}^* L & \xrightarrow{p_{124}^* f} & p_{14}^* L \end{array}$$

commutes.

A **connective structure** on a bundle gerbe (also known as **connection and curving** on a bundle gerbe) is

- a connection ∇ on L
- a 2-form $\omega \in \Omega^2(Y)$ on Y

such that on $Y^{[2]} \rightrightarrows_{p_1}^{p_2} Y$ the equation

$$p_2^*\omega - p_1^*\omega = F_\nabla$$

holds.

Lemma 4 (p,i) -transition tetrahedra are in bijection with line bundle gerbes with connection and curving.

Proof. Using the above notation, identify Y with \mathcal{U} . By prop. ?? the trivialization transition g defines a line bundle with connection on $\mathcal{U}^{[2]}$ and vice versa. Hence identify

$$g \leftrightarrow (L, \nabla).$$

The picture obtained is

$$\begin{array}{ccc} \begin{array}{c} g \\ \downarrow \\ \mathcal{U}^{[2]} \rightrightarrows \mathcal{U} \\ \downarrow \\ M \end{array} & \leftrightarrow & \begin{array}{c} L \\ \downarrow \\ Y^{[2]} \rightrightarrows Y \\ \downarrow \\ M \end{array} \end{array}$$

Identify the gerbe product with the inverse of the modification f using the third item of prop. ?. By prop. ?? this does satisfy the required associativity condition.

In order to match the connection data, observe that the line-2-bundle $\text{tra}_{\mathcal{U}}$ is trivial by assumption and hence defines, according to def. ??, a global 2-form B on \mathcal{U} . Identify this 2-form with the curving ω of the bundle gerbe. Prop. ?? says that $\text{tra}_{\mathcal{U}}$ and (L, ∇) satisfy the condition of a gerbe connection

$$p_2^*B - p_1^*B = F_\nabla.$$

□

Definition 2 (Murray,Stevenson) Given two bundle gerbes with connective structure (L, Y) and (L', Y) a **stable isomorphism**

$$(L, Y) \xrightarrow{(H, \mathcal{E})} (L', Y)$$

is a line bundle with connection $H \longrightarrow Y$ together with an isomorphism

$$p_1^*H \otimes L \xrightarrow{\varepsilon} L' \otimes p_2^*H$$

of line bundles with connection on $Y^{[2]}$ satisfying

$$\begin{array}{ccc}
 p_1^*H \otimes p_{12}^*L \otimes p_{23}^*L & \xrightarrow{p_{12}^*\varepsilon \otimes \text{Id}_{p_{23}^*L}} & p_{12}^*L' \otimes p_2^*H \otimes p_{23}^*L & (3) \\
 \downarrow \text{Id}_{p_1^*H} \otimes f & & \searrow \text{Id}_{p_{12}^*L'} \otimes p_{23}^*\varepsilon & \\
 p_1^*H \otimes p_{13}^*L & \xrightarrow{p_{13}^*\varepsilon} & p_{13}^*L' \otimes p_3^*H & \\
 & & \swarrow f' \otimes \text{Id}_{p_3^*H} & \\
 & & p_{12}^*L' \otimes p_{23}^*L' \otimes p_3^*H &
 \end{array}$$

Lemma 5 *1-morphisms in $\text{Tra}(p, i)$ are in bijection with stable isomorphisms of bundle gerbes.*

Proof. According to def.?? a 1-morphism of pre-trivializations comes with a 2-morphism (??) of trivial line-2-bundles. According to prop. ?? this line-2-bundle 2-morphism defines an isomorphism of line bundles with connection

$$p_1^*h \otimes g' \xrightarrow{\bar{\varepsilon}_g} g \otimes p_2^*h$$

The tin can equation (??) is then equivalent to the compatibility condition 3. \square
